The antigenicity of purified flagellin prepared from the single polar flagellum of *Vibrio parahaemolyticus* was found to be common to that of all strains tested, i.e., *V. alginolyticus*, *V. cholerae*, *V. anguillarum*, *V. piscium*, *V. ichthyo-dermis*, *Beneckea natriegens*, *B. campbellii*, *B. nereida*, *B. pelagia*, and *B. neptuna*. On the other hand, the antigenicity of purified flagellin prepared from the lateral flagella of *V. parahaemolyticus* was common to that of *V. alginolyticus* but not to that of *B. campbellii* or *B. neptuna*. Some physicochemical properties of flagellin from the single polar flagellum of *V. parahaemolyticus* were found to be similar to those of flagellins from other strains, such as those of *V. anguillarum* and *B. neptuna*.

*Vibrio parahaemolyticus* possesses lateral flagella in addition to a polar monotrichous flagella in addition to a single polar flagellum under certain culture conditions (1, 3, 4, 16-18). (In previous papers from this laboratory [8, 11-13], lateral flagella were described as peritrichous. However, to distinguish them from the flagella of true peritrichous cells, such as those found in *Enterobacteriaceae*, we use the term lateral flagella in this paper.) Previously, we reported an antigenic difference between the polar and lateral flagella of *V. parahaemolyticus* (8, 12, 13). In addition to the antigenic difference, several other different properties of these two flagella were reported. Lateral flagella were produced only on agar plates (3, 17, 18) and were easily removed from the cells mechanically (17, 18), whereas the single polar flagellum was produced either in liquid medium or on agar plates (3, 17, 18) and could only be removed from the cells by vigorous agitation (7). The single polar flagellum has a sheath-like structure, whereas the lateral flagella do not (1, 7, 17, 18). Moreover, lateral flagella are of the curly type, whereas the single polar flagellum is a normal type (17, 18).

This paper reports studies on the distribution of these two kinds of flagellar antigens in various species of the genus *Vibrio* and related genera.

**MATERIALS AND METHODS**

Strains and growth media. The *Vibrio* and *Beneckea* strains used are listed in Table 1. (The genus *Beneckea* is not recognized in Bergey's *Manual of Determinative Bacteriology* (8th ed.); it is described as a genus of uncertain taxonomic position. In this paper, we adopted the proposal of Baumann et al. [3] for the species of the genus *Beneckea.*) Modified MOF (MMOF) medium contains the following constituents (grams per liter): Casitone (Difco), 1; yeast extract (Difco), 4.5; tris(hydroxymethyl)aminomethane, 0.5; boric acid, 0.011; ammonium sulfate, 0.5; disodium phosphate, 0.004; ammonium nitrate, 0.0008; sodium chloride, 9.7; magnesium chloride, 4.4; sodium sulfate, 1.6; potassium chloride, 0.275; sodium bicarbonate, 0.08; potassium bromide, 0.04; strontium chloride, 0.017; sodium silicate, 0.002; and sodium fluoride, 0.0012 MMOF agar contains 20 g of agar (Difco) per liter in addition to the above-mentioned components. The medium was adjusted to pH 7.5.

Preparation of crude flagellin solution. Cells grown overnight at 25 °C on plates containing 20 ml of MMOF agar were suspended in 2 ml of 0.01 M phosphate buffer (NaHPO₄-KH₂PO₄, pH 7.0) containing 0.9% NaCl and heated at 65 °C for 10 min to solubilize the flagella. The mixture was centrifuged at 9,000 × g for 15 min, and the supernatant was used as the crude flagellin solution. Cells of *V. cholerae* were mixed with 3% phenol and then dialyzed before being heated.

Preparation of purified flagellin. The procedures used for purification of flagella were essentially as described previously (7, 13). Cells were grown on MMOF agar at 25 °C overnight, and then their flagella were removed by vigorous agitation in a Waring blender (8,000 rpm for 5 min). The flagella from each strain were purified by differential centrifugation, treatment with diethylaminoethyl-cellulose, and zone electrophoresis on Pevikon C-870, as described previously (7, 13). The flagellins were then prepared from the purified flagella and filtered through a Sephadex G-100 column. Each type flagellin was subjected to hydroxyapatite column chromatography.
Preparation of anti-flagellin antiserum. A solution of about 200 µg of purified flagellin in 5 ml of 0.01 M phosphate buffer (pH 7.0) was emulsified with an equal volume of Freund incomplete adjuvant (Difco). The emulsion was inoculated intramuscularly into rabbits weighing 2.5 to 3 kg. After 2 weeks, the rabbits were again inoculated with the same amount of emulsion. Two additional intravenous injections of 2 ml of flagellin (100 µg) were then given at intervals of 1 week; antiserum was obtained 1 week after the final immunization.

Gel diffusion test. The plate method of Ouchterlony (9) was used for the gel diffusion test with 0.7% agar (Noble; Difco) in 0.01 M tris(hydroxymethyl)-aminoethane-hydrochloride buffer (pH 7.0). Samples were put into the wells, and the plates were placed in a humidified incubator at 37°C.

Assay of protein and phosphate ion concentration. Protein concentration was determined by the method of Lowry et al. (5), and the phosphate ion concentration was determined by the method of Baginski et al. (2).

Analysis of the amino acid composition of flagellin. About 500 µg of flagellin was hydrolyzed with 2 ml of 6 N hydrochloric acid at 105°C for 12 h in a sealed glass tube. The mixture was dried in a vacuum evaporator, the residue was dissolved in 2 ml of 0.2 M citrate buffer (pH 2.2), and a 0.5-ml sample was examined in a Hitachi amino acid analyzer, model KLA-5.

RESULTS

Antigenicities of flagellins from various species of the genera Vibrio and Beneckeja. Motile strains of V. parahaemolyticus, of the six species of the genus Vibrio, and of the five species of the genus Beneckeja listed in Table 1 were selected on soft-agar media to test the antigenicities of their flagellins. These strains were grown on MMOF agar plates, and crude flagellin solutions were prepared from them and subjected to the gel diffusion test, using antisera against flagellin of V. parahaemolyticus WP-1.

Antiserum against purified flagellin of single polar flagella (M flagellin) of V. parahaemolyticus WP-1 gave a common precipitin line with the crude flagellin solutions of all strains examined, indicating that all 18 strains have antigenically homogeneous M flagellin. Some of the results are shown in Fig. 1. It can be seen that two strains of V. cholerae, V. anguillarum, B. neptuna, and B. natriegens formed a common precipitin line against the anti-M flagellin antiserum of V. parahaemolyticus WP-1.

Among the 18 strains examined, V. parahaemolyticus, V. alginolyticus, B. campbellii, and B. neptuna formed lateral flagella when grown on solid media, in addition to a single polar flagellum (3, 4, 13, 17, 18). The antigenicities of crude flagellin solutions of these strains were examined in the agar gel diffusion test with antisera against purified lateral flagellin (L flagellin) of V. parahaemolyticus WP-1. V. alginolyticus contained L flagellin antigeni-
cally identical to *V. parahaemolyticus* L flagellin, whereas crude flagellin solutions of *B. campbellii* and *B. neptuna* did not form any precipitin line with anti-L flagellin antiserum of *V. parahaemolyticus* WP-1 (Fig. 2). Moreover, L flagellin of *B. campbellii* and *B. neptuna* did not react with heterologous anti-L flagellin antiserum (Fig. 3).

These results indicate that the antigenicity of the single polar flagellum of various species of the genera *Vibrio* and *Beneckea*, including *V. parahaemolyticus*, *V. alginolyticus*, *V. cholerae*, *V. anguillarum*, *V. piscium*, *V. ichthyodermis*, *B. natriegens*, *B. campbellii*, *B. nereida*, *B. pelagia*, and *B. neptuna*, is homologous, whereas the antigenicities of lateral flagella of the different species all differ from each other, except for the lateral flagella of *V. parahaemolyticus* and *V. alginolyticus*, which share the same antigenicity.

Some physicochemical properties of flagellins from various species of the genera *Vibrio* and *Beneckea*. When the purified flagellin was subjected to hydroxyapatite column chromatography, two distinct peaks were obtained with the flagellins of *V. parahaemolyticus* and *B. neptuna* (Fig. 4A and C). On the other hand, the flagellin of *V. anguillarum* gave a single peak upon hydroxyapatite column chromatography (Fig. 4B). On the basis of our previous data (13), the peak eluted with the lower concentration of phosphate ion is derived from lateral flagella, and that eluted with the higher concentration is derived from single polar flagella.

To determine the molecular weights of the flagellins from single polar flagella of these three strains, the flagellins were subjected to Sephadex G-100 gel filtration. All of these flagellins eluted in the same position, indicating that they have similar molecular weights (Fig. 5). Previously we reported that the molecular weight of flagellin from single polar flagella of *V. parahaemolyticus* is about 40,000 (11), so it is concluded that the molecular weights of the flagellins of single polar flagella of *V. anguillarum* and *B. neptuna* are also about 40,000.

Table 2 shows the amino acid compositions of the flagellins from single polar flagella of *V. parahaemolyticus* WP-1, *V. anguillarum* NCMB 829, and *B. neptuna* ATCC 25919. The amino acid compositions of these three flagellins are, in general, very similar.

From these results it is concluded that single polar flagella of various species of *Vibrio* and *Beneckea* have not only homologous antigenicity but also similar physicochemical properties.

**DISCUSSION**

In this work the antigenicities of single polar flagella and lateral flagella of various species of the genera *Vibrio* and *Beneckea* were studied.
It was found that the single polar flagellum of *V. parahaemolyticus* had the same antigenicity as that of the single polar flagella of strains of *V. alginolyticus, V. cholerae, V. anguillarum, V. piscium, V. ichthyodermis, B. natriegens, B. campbellii, B. nereida, B. pelagia*, and *B. neptuna*.

Although it has been reported that *V. parahaemolyticus* and *V. alginolyticus* possess the same H antigen (6, 15), several workers have concluded that there is no H antigen common to different species of the genus *Vibrio* (10, 14, 15). Terada (15) reported that the H antigen of *V. parahaemolyticus* was different from that of *V. cholerae, V. anguillarum*, and some strains of *Vibrio* species that do not agglutinate with anti-*V. cholerae* antiserum (so-called NAG vibrio). Sakazaki et al. (10) also reported that there is an H antigen common to different strains of *V. cholerae* and some *Vibrio* species but that this antigen is not homologous with the H antigen of *V. parahaemolyticus* and *V. anguillarum*. Smith (14) reported no evidence for an H antigen common to *V. cholerae* and some *Vibrio* species described by Sakazaki et al. (10). These workers reached their conclusions from the results of H agglutination tests on the cells; they did not apply the gel diffusion technique used in this work. We assume that their data indicating that there is no common H antigen was due to the low titer of antisera, because antigen used for immunization contained very little flagellar protein. It is also probable that even the antiserum with the high titer against *V. cholerae* flagella does not react with *V. parahaemolyticus* since it has a sheath-
like structure on its single polar flagellum (1, 7, 17, 18).

The physicochemical properties of the flagellins of single polar flagella suggested that flagella of various species of the genera *Vibrio* and *Beneckea* possess the same protein moiety and that they may share the same antigen determinants.

It is interesting that, among the lateral flagella of the different species examined, only *V. parahaemolyticus* and *V. alginolyticus* have homogeneous antigenicity. Each species seems to possess its own specific antigenicity. If so, it may be possible to identify a bacterium by using the specific antiserum against its lateral flagella. Experiments on this are now in progress in our laboratory.

ACKNOWLEDGMENT

We would like to express our thanks to M. Makita for valuable discussion.
