Haemophilus influenzae is a V factor-dependent species. A plasmid conferring V factor independence in Haemophilus parainfluenzae and Haemophilus ducreyi was transferred to plasmid-free H. influenzae Rd by DNA transformation. The growth characteristics of the transformants in a complex and a chemically defined medium were compared, and the ability of several exogenous pyridine nucleotides and precursors to support growth was examined. Although the transformants appeared to be V factor independent in a complex medium, in a chemically defined medium they exhibited both V factor-dependent and nicotinamide-dependent growth. Because of the inability of the plasmid-free H. influenzae Rd to utilize nicotinamide for growth, it was concluded that the genes conferring this function were plasmid linked. Our results indicate that the V factor requirement, as it is presently defined, is not suitable to serve as a definitive taxonomic criterion for species determination in the family Pasteurellaceae.

MATERIALS AND METHODS

Bacterial strains and media. The strains used in this study are listed in Table 1. The H. parainfluenzae isolates were grown in brain heart infusion (BHI) broth and BHI agar (Becton Dickinson) unsupplemented with NAD. For the growth of H. influenzae Rd the above-mentioned media were supplemented with 10 μg of hemin (Sigma) per ml and 2 μg of NAD (Sigma) per ml. The V factor-independent transformants of H. influenzae Rd were grown in hemin-supplemented BHI broth and agar as well as in the chemically defined medium (CDM) developed by Herriott et al. (8). The following pyridine compounds supplied by Sigma were added to CDM to examine their ability to support the growth of the V factor-independent transformants of H. influenzae Rd: NAD, NAM, NA, nicotinic acid mono-nucleotide (NAMN), nicotinic acid adenine dinucleotide (NAAD), and QA. The H. ducreyi strains were grown on the enriched agar medium described by Nsanze et al. (16) in 5% CO 2 at 35°C except the type strain, CIP 542 T, which was grown on chocolate agar.

Growth in CDM. Frozen BHI cultures of H. influenzae Rd or the V factor-independent transformants were diluted 1:50 in 10-ml aliquots of hemin-supplemented BHI broth in 250-ml flasks. These cultures were incubated for about 5 h at 37°C with agitation at 200 rpm on a gyratory shaker until they reached an optical density at 650 nm of 1.0. The cells were harvested by centrifugation, washed twice with 10 ml of CDM, and resuspended in 10 ml of CDM. Aliquots of CDM in 500-ml flasks were inoculated with the resuspended cells (0.2 ml in 20 ml of CDM) and incubated for 5 h in the absence of pyridine compounds. The filter-sterilized pyridine compounds were added to the starved cells to give a final concentration of 5 μM, and incubation was continued as described above. Samples were taken at different intervals and plated onto hemin-supplemented BHI agar to determine the number of CFU per ml over a 20-h period.

Growth in complex medium. The inoculum was prepared as described in the previous paragraph. Duplicate 20-ml aliquots of hemin-supplemented BHI broth, one with 5 μM NAD added and one without any NAD, were inoculated with 0.2 ml of washed and resuspended cells and incubated

* Corresponding author.
at 37°C with shaking at 200 rpm. The number of CFU per ml was determined as described above.

**DNA transformation.** Purified plasmid DNA was prepared by the alkaline lysis method described by Sambrook et al. (18) with the addition of a phenol-chloroform extraction step. Competence in *H. influenzae* Rd was induced by the static aerobic procedure of Gromkova et al. (7). For the transformation assay, 0.1 ml of competent cells and 0.8 ml of BHI broth supplemented with NAD, hemin, and 1 mM MgSO₄ were added to 0.1 ml of purified DNA at a saturating concentration of 1 µg/ml. This mixture was incubated for 5 h at 37°C, and then the culture was diluted and plated in triplicate on BHI agar unsupplemented with NAD for selection of the transformants. Control cultures with no added DNA were tested to check for spontaneous mutants.

**RESULTS**

**Transformation of *H. influenzae* Rd to V factor independence.** Plasmids conferring V factor independence in *H. parainfluenzae* and *H. ducryei* were transferred to a plasmid-free *H. influenzae* Rd strain by DNA transformation. *H. influenzae* Rd is a nonencapsulated (rough) segregant of an encapsulated (smooth) serotype d strain. It was chosen as a recipient because it is highly transformable (1) and it is able to grow in CDM. This medium was developed by Herriott et al. (8) specifically for *H. influenzae* Rd. Growth in this medium is important because it allows the determination of exogenous pyridine compounds required for growth. Four naturally occurring V factor-independent isolates of *H. parainfluenzae* and five *H. ducryei* strains (two reference and three clinical) were used as a source of plasmid DNA (Table 1). Transformants were selected for their ability to grow on BHI agar without the addition of NAD. Each transformant acquired a small 5.25-kb plasmid. Fig. 1 presents the electrophoretic mobility of two representative plasmids acquired by transforming *H. influenzae* Rd with plasmid DNA from *H. parainfluenzae* 9 and *H. ducryei* ATCC 27722. Details on the transforming activity and other properties of the plasmid conferring V factor independence are described elsewhere (24, 25).

**Kinetics of growth of the V factor-independent transformants of *H. influenzae* Rd in a complex medium.** To study whether the presence of a plasmid conferring V factor independence had an effect on the kinetics of growth of *H. influenzae* Rd in a complex medium, one V factor-independent transformant of *H. influenzae* Rd obtained by using DNA from each of the donor strains listed in Table 1 was examined for its ability to grow in BHI broth in both the presence and absence of NAD. Figures 2a and b present the growth curves of two representative transformants of *H. influenzae* Rd. Although the source of the plasmid in these transformants was different (Table 1), their growth curves exhibited similar profiles. Because of their ability to grow equally well in BHI broth in the presence and absence of NAD, the transformants were designated V factor independent. The growth curves of the remaining seven transformants were similar to those presented in Fig. 2a and b. The generation times of all transformants in unsupplemented and NAD-supplemented broth were in the range of 38 to 45 min and 40 to 51 min, respectively. The generation time was determined by using the linear portion of the growth curve. Unlike the transformants, the isogenic plasmid-free *H. influenzae* Rd was not able to grow in the absence of NAD (Fig. 2c). The generation time of this strain in NAD-supplemented broth was 45 min.

It has been previously demonstrated that spontaneous loss of the plasmid conferring V factor independence in *H. influenzae* Rd transformants occurs at a frequency of 0.1 to 0.2% of the progeny of a single clone (24). Our results show that the segregation to V factor dependence does not appear to have an effect on the growth curves in the absence of NAD (Fig. 2a and b).

**Kinetics of growth of the V factor-independent transformants of *H. influenzae* Rd in CDM.** Two approaches have been used to determine the kinetics of growth of the V factor-independent transformants of *H. influenzae* Rd. One is the static aerobic procedure of Gromkova et al. (7), and the other is the liquid method of L. Slaney, University of Manitoba, Winnipeg, Manitoba, Canada.
previously been used for studying the biosynthetic pathway of NAD and the requirement for exogenous pyridine nucleotides. The first approach is to examine cell extracts for their ability to synthesize NAD and to identify the enzyme activities required for this synthesis (3, 9). The second approach, used in the present study, is to simply test exogenous pyridine nucleotides or precursors for their ability to support growth in a CDM (14). The pyridine compounds employed in this study were added to the CDM after 5 h of starvation of the cells. No increase in the optical density of the cells was observed during the starvation period. All nine *H. influenzae* Rd transformants tested were able to grow in the presence of NAD, NMN, and NAm, and their growth curves showed similar profiles. The growth curves of two representative V factor-independent transformants and those of the plasmid-free *H. influenzae* Rd in the presence and absence of exogenous pyridine compounds are presented in Fig. 3a, b, and c, respectively. Generation times of transformants in the presence of pyridine compounds were 51 to 63 min with NAD, 53 to 65 min with NMN, and 55 to 63 min with NAm. Unlike the transformants, the plasmid-free *H. influenzae* Rd failed to grow in the presence of NAm; however, NAD and NMN did support its growth (Fig. 3c). The generation time of *H. influenzae* Rd was 60 min in the presence of either NAD or NMN. Neither the plasmid-free *H. influenzae* Rd nor the transformants carry-
FIG. 3. Growth curves of *H. influenzae* Rd and V factor-independent transformants in CDM supplemented with NAD (■), NMN (▲), or NAm (▲) or unsupplemented (□). (a) Transformant with pH9; (b) transformant with pHD27722; (c) plasmid-free *H. influenzae* Rd.

...ing the 5.25-kb plasmid were able to grow in unsupplemented CDM or in CDM containing NAAD, NAMN, NA, or QA (data not presented in Fig. 3a, b, or c), suggesting that these strains were incapable of de novo NAD biosynthesis.

It is of interest that in CDM the *H. influenzae* Rd transformants exhibit V factor-dependent growth (Fig. 3a and b), whereas in BHI broth their growth appears to be V factor independent (Fig. 2a and b). This was probably due to the presence of NAm in BHI broth (14). The growth in CDM of two *H. influenzae* Rd transformants that have lost the small plasmid was also examined. The growth curves of these isolates (data not presented) were similar to those of the original plasmid-free *H. influenzae* Rd recipient strain (Fig. 3c). The correlation between the loss of the plasmid and the loss of the ability to utilize NAm for growth supports the conclusion that the genes coding for utilization of NAm are plasmid linked.

**DISCUSSION**

Previous study on the biosynthetic pathway of NAD of the V factor-independent species *Haemophilus haemoglobinophilus* has revealed that NAm is the sole source of NAD in this organism and that NAD is synthesized directly from NAm via NMN (10). Recent investigation on the growth requirements in CDM of *Actinobacillus pleuropneumoniae*
biotype 2 has provided evidence that this biotype shows both V factor-dependent and NAm-dependent growth (14). However, in a complex medium *A. pleuropneumoniae* biotype 2 appears to be V factor independent (17). Data presented in this paper show that the growth requirements in CDM of *H. influenzae* Rd transformants that have acquired the small 5.25-kb plasmid from *H. parainfluenzae* and *H. ducreyi* donors are similar to those of *A. pleuropneumoniae* biotype 2 (Fig. 3a and b) while the plasmid-free *H. influenzae* Rd (Fig. 3c), like *A. pleuropneumoniae* biotype 1, is able to utilize only V factor for growth (14). In both systems the only difference in the growth of the V factor-dependent and the V factor-independent strains is the ability of the latter to utilize NAm. This suggests that the genetic differences between the V factor-dependent and the V factor-independent strains are not as significant as has been previously thought. Other examples of V factor-independent bacteria of the family *Pasteurellaceae* that require NAm for growth are *Pasteurella multocida* (12), *Pasteurella haemolytica* (19, 20), and *Pasteurella ureae* (21, 22). *P. multocida* has also been shown to exhibit V factor-dependent growth (2). These data illustrate that, within the family *Pasteurellaceae*, the requirement for exogenous pyridine nucleotides or precursors is not confined to the genus *Haemophilus* but, rather, may be characteristic of the family as a whole (15).

No previous information about the location of the genes involved in NAD biosynthesis in members of the family *Pasteurellaceae* is available. Four unusual V factor-independent *H. parainfluenzae* isolates (Table 1) were the first bacterial strains in which the genes coding for V factor independence were located on a small 5.25-kb plasmid (Fig. 1) (24). Subsequently, a plasmid of a similar size also conferring V factor independence was recovered from *H. influenzae* Rd transformants with *H. ducreyi* DNA (Fig. 1) (25). In this paper we present evidence that the V factor independence is due to the ability of the cells to utilize NAm for growth and that the genes coding for this function are plasmid linked in *H. parainfluenzae* and *H. ducreyi*. Because of the small size of this plasmid, NAD is most probably synthesized directly from NAM by a pathway similar to that described for *H. haemoglobinophilus* (10). It would be of interest to determine whether the genes coding for V factor independence in other members of the family *Pasteurellaceae* are also plasmid linked. Although no published information about the location of the genes coding for the utilization of V factor is available, they appear to be of chromosomal nature because of their stability.

The recovery from natural sources of both V factor-dependent and V factor-independent isolates from species belonging to two different genera, *Haemophilus* (6) and *Actinobacillus* (17), indicates that the V factor requirement is variable among strains of the same species and is not suitable as a taxonomic criterion for species determination. In addition, the demonstration that in at least two *Haemophilus* species the genes conferring V factor independence are plasmid linked (24, 25) suggests that other V factor-dependent species have the potential to become V factor independent because of the mobility of extrachromosomal genes or conversely, some V factor-independent isolates may become V factor dependent because of loss of the plasmid. We were able to demonstrate transfer of the plasmid conferring V factor independence between both homologous and heterologous species by DNA transformation (6, 24).

In a recent review Niven and O’Reilly analyzed the biochemical basis of the V factor requirement in three genera of the family *Pasteurellaceae*, *Haemophilus*, *Pasteurella*, and *Actinobacillus*, and concluded that a common characteristic of these genera is the lack of de novo NAD biosynthesis and the ability to grow in the presence of a few exogenous pyridine nucleotides or precursors (15). The authors propose the inclusion of NAm in the pyridine compounds that may serve as a V factor. This will allow the classification of all members of the family *Pasteurellaceae* as V factor dependent. We agree with the opinion of Niven and O’Reilly that the definition of the V factor needs to be revised. However, in view of the extrachromosomal nature of the genes coding for NAm utilization in at least two *Haemophilus* species, we feel that it would be more appropriate to preserve the old definition of V factor and to include NAm as an additional pyridine compound that can be utilized for growth by any member of the family *Pasteurellaceae*. Thus a member of this family can be V factor dependent or NAm dependent or both. Because of the presence of NAm and other pyridine compounds in complex media, these media are not suitable for the determination of the growth requirements. They can be used only for initial screening of species of *Haemophilus* and *Actinobacillus* that are presently classified as V factor dependent, and if a strain appears to be V factor independent, it should be tested in synthetic or semisynthetic media for proper determination of the growth requirements. Although the frequency of the naturally occurring V factor-independent *H. parainfluenzae* isolates appears to be low (23), one should be aware of the possible spread of the plasmid conferring V factor independence to other V factor-dependent species. According to present laboratory practice, isolates that are V factor independent cannot be identified as *H. parainfluenzae* or *H. influenzae*. This definition could interfere with the identification of strains that may be clinically important.

To satisfy the taxonomist, the microbial physiologist, and the clinical microbiologist, this question should be further debated in order to find a proper definition for V factor.
