Taxonomic Study of Bacteria Isolated from Plants: Proposal of
*Sphingomonas rosa* sp. nov., *Sphingomonas pruni* sp. nov.,
*Sphingomonas asaccharolytica* sp. nov., and
*Sphingomonas mali* sp. nov.

MARIKO TAKEUCHI,1,*, TAKESHI SAKANE,1 MIYOKO YANAGI,2† KAZUHIDE YAMASATO,2‡ KOEI HAMANA,3 and AKIRA YOKOTA1§

Institute for Fermentation, Osaka, Yodogawa-ku, Osaka 532,1 Institute of Applied Microbiology,8 The University of Tokyo, Yayoi, Bunkyo-ku, Tokyo 113,9 and College of Medical Care and Technology, Gunma University, Maebashi-shi, Gunma 371,3 Japan

The taxonomic positions of 10 strains of 3-ketolactose-forming bacteria which were isolated from the roots of plants (*Rosa* sp., *Psychrotia nairobiensis*, *Ardisia crispa*, *Prunus persica*, and apple trees) were investigated. The DNA base compositions of these strains ranged from 64.0 to 65.7 mol%, the isoprenoid quinone of each strain was ubiquinone 10, 3-hydroxy fatty acids were lacking in the cellular fatty acids of these organisms, and all of the strains contained a sphingolipid with the long-chain base dihydroxyphosphosinogin. These are characteristics of the genus *Sphingomonas*. On the basis of morphological, physiological, and chemotaxonomic characteristics, together with DNA-DNA hybridization and 16S rDNA sequence comparison data, we propose the following four new species of the genus *Sphingomonas*: *Sphingomonas rosa* (type strain, IF0 15208) for the strains isolated from rose plants and formerly named [Agrobacterium rhizogenes]; *Sphingomonas pruni* (type strain, IF0 15498) for the strains isolated from *Prunus persica*; and *Sphingomonas asaccharolytica* (type strain, IF0 15499) and *Sphingomonas mali* (type strain, IF0 15508) for the strains isolated from apple trees. Two strains which were isolated from *Psychrotria nairobiensis* and formerly named [Chromobacterium lividum] were identified as *Sphingomonas yanoiukiya* strains.

3-Ketolactose-forming activity (2) has been found only in biovar 1 strains of the genus *Agrobacterium* (3, 10), and this characteristic has proven to be a useful taxonomic marker for agrobacteria. Holmes and Roberts (8) proposed an identification scheme for agrobacteria based on 84 phenotypic tests. Fifty *Agrobacterium* strains, mostly strains maintained in the National Collection of Pathogenic Bacteria, were separated into four clusters on the basis of the results of a numerical analysis. Holmes and Roberts suggested that a small group of "yellow-pigmented, 3-ketolactose positive bacteria," including [Agrobacterium rhizogenes] NCPPB 2661, NCPPB 2662, and NCPPB 2663, which were isolated from hairy roots of *Rosa* sp., and [Chromobacterium lividum] NCTC 10590 and NCTC 10591, which were isolated from *Psychrotria nairobiensis* or *Ardisia crispa*, may constitute another distinct group of agrobacteria (brackets indicate taxa that are misnamed). The results of rRNA cistron similarity studies indicated that these strains are more closely related to Flavobacterium capsulatum than to the genus *Agrobacterium* (1). *F. capsulatum* was subsequently transferred to the genus *Sphingomonas* as *Sphingomonas capsulata* by Yabuuchi et al. in 1990 (27). The genus *Sphingomonas* was proposed by Yabuuchi et al. (27), and the description of this taxon has recently been emended by us (20). Members of the genus *Sphingomonas* are yellow-pigmented, nonfermentative, gram-negative, nonmotile or motile rods with a single polar flagellum and are characterized by the presence of a large amount of a unique sphingolipid with the long-chain base dihydroxyphosphosinogin, by the presence of 2-hydroxymyristic acid (2-OH 14:0), by the absence of 3-hydroxy fatty acids, and by the presence of ubiquinone 10 (Q-10). Therefore, we examined the taxonomic positions of the five strains of yellow-pigmented 3-ketolactose-positive bacteria described by Holmes and Roberts (8). An additional five strains of 3-ketolactose-positive bacteria, which were isolated from plants and were designated agrobacterium-like strains, were also studied.

In this paper, we report both the phenotypic and chemotaxonomic characteristics of 3-ketolactose-positive bacteria and the results of a comparison of the 16S rRNA gene (rDNA) sequences of these organisms with the sequences of previously described species of the genus *Sphingomonas* (20, 27) and *Rhizomonas suberi-faciens* (23). On the basis of phenotypic data, DNA-DNA hybridization data, and the results of the 16S rDNA sequence analysis, we propose four new species of the genus *Sphingomonas*.

**MATERIALS AND METHODS**

**Microorganisms and cultures.** The strains which we used are listed in Table 1. The type strains of *Sphingomonas* species and two strains of *Rhizomonas suberi-faciens* (23) were used for a comparison of taxonomic characteristics. All of the strains except the *Rhizomonas suberi-faciens* strains were cultured at 28°C with aerobic shaking in PY medium containing 1% peptone, 0.2% yeast extract, 0.2% NaCl, and 0.2% glucose (pH 7.0). *Rhizomonas suberi-faciens* IFO 152117 (T = type strain) and IFO 15212 were cultured at 28°C with aerobic shaking in PG medium containing 0.5% peptone, 0.25% glucose, 0.13% K2HPO4, 0.05% MgSO4·7H2O, 0.05% KNO3, and 0.006% Ca(NO3)2·4H2O (pH 7.2).

**Determination of phenotypic characteristics.** Cultures were grown on PY or

PG medium containing 1.5% agar. API 20NE tests (API, La Balme les Grottes, Montalieu Vercieu, France) were used to determine physiological and biochemical characteristics. API AUX medium containing 0.2% carbohydrates was used to determine carbohydrate assimilation, and pepton yeast extract-phenol red medium (26) containing 0.2% carbohydrates was used to determine acid production. The 3-ketolactose test (formation of 3-ketolactose from lactose) was carried out by the method of Bernaerts and De Ley (3). Quantitative determination of 3-ketolactose was performed by high-performance liquid chromatography (HPLC) (12) as described previously (22). The method used to identify 3-ketolactose from Sphingomonas strains is described in the accompanying paper (15).

Determination of chemotaxonomic characteristics. Analyses to determine cellular fatty acids, sphingolipids, isoprenoid quinones, and G+C contents of DNA and rRNA hybridization experiments were performed as described previously (20). Polyamines were analyzed by HPLC as described previously (6).

16S rDNA sequence determination and analysis. Wet cells (1 to 3 mg) were suspended in 300 μl of InstaGene purification matrix (Bio-Rad Co., Ltd., Richmond, Calif.), incubated at 56°C for 15 to 30 min, sonicated at 100 W for 30 s, and heated for 5 min. After centrifugation at 1,000 × g for 2 to 3 min, the supernatant was subjected directly to PCR amplification (7) by using the Taq polymerase kit (Cetus, Inc., Norwalk, Conn.). The purified PCR products of isolates Y-250T (= IFO 15498T), Y-345T (= IFO 15499T), and Y-347T (= IFO 15500T) were sequenced by using a Sequenase kit for sequencing (United Biochemicals, Inc., Cleveland, Ohio) (16) and the following four primers: primer 350R, covering the sequence from position 342 to position 357 [Escherichia coli numbering (4)]; primer 520R, covering the sequence from position 517 to position 531; primer 920R, covering the sequence from position 907 to position 924; and primer 1400R, covering the sequence from position 1392 to position 1406. The 16S rDNA sequences of [A. rhizogenes] IFO 15208 (= IAM 14222) and [C. lividum] IFO 15163 (= IAM 14225) were determined with a model 373A automated DNA sequencer (Applied Biosystems Co., Ltd., Foster City, Calif.) and a Dye Primer Cycle sequencing kit, using dye primer 21M13 (Applied Biosystems) as described previously (28). DNA sequences were aligned by using the Oden program (9). Nucleotide substitution rates (K MI values) were calculated (11), and a phylogenetic tree was constructed by the neighbor-joining method (14). The sequences were aligned with previously published sequences obtained from DNA databases.

Nucleotide sequence accession numbers. The accession numbers of the sequences used for comparison with the sequences which we determined are as follows: Erythrobacter longus, M59062; Roseobacter denitrificans, M96746; Porphyromonas aquatilis IFO 13935T, D13725; Sphingomonas paucimobilis IFO 15100T, D13724; Sphingomonas adhaesiva, GUP11458, D16146; Sphingomonas sanguis IFO 13937T, D13726; S. capsulata, M59296; Sphingomonas yanoikuyae IFO 15102T, D13728; Sphingomonas terreus IFO 15096T, D13727; Sphingomonas macrogolipidur IFO 15033T, D13723; and Rhizomonas subfaciens IFO 15211T, D13737. The nucleotide sequence data for new species of the genus Sphingomonas and other sequences which we determined have been deposited in the DNA Data Bank of Japan database under the following accession numbers: Sphingomonas asaccharobutyrica IF0 15499T, D28571, D28572, and D28573; Sphingomonas mali IFO 15507T, D28574, D28575, and D28576; Sphingomonas pruni IFO 15498T, D28568, D28569, and D28570; Sphingomonas rosa [A. rhizogenes] IFO 15208, D13945; and S. yanoikuyae [C. lividum] IFO 15163, D13946.

RESULTS

Morphological, physiological, and biochemical characteristics. All of the strains which we studied were gram-negative, motile rods. As shown in Table 2, all of the strains gave positive results in tests for 3-ketolactose production, β-galactosidase activity, esculin hydrolysis, and assimilation of maltose and xylose, and all of the strains gave negative results in tests for arginine dihydrolase activity, urease activity, production of indole, and assimilation of adonitol, inositol, malonate, mannositol, oxalate, sorbitol, and tartrate. The 10 strains were separated into five groups on the basis of their phenotypic characteristics. The first group consisted of three [A. rhizogenes] strains; the second group consisted of two [C. lividum] strains; the third and fourth groups each contained a single agrobacterium-like isolate (Y-250T [= IFO 15498T] and Y-345T [= IFO 15500T]); and the fifth group consisted of strains Y-347T (= IFO 15500T), Y-348 (= IFO 15501T), and Y-351 (= IFO 15502T).

Chemical characteristics. The chemical characteristics of the test strains are summarized in Tables 3 and 4. All of the strains contained ubiquinone Q-10, and the DNA base compositions ranged from 64.0 to 65.9 mol%. All of the strains contained sphingolipids, and the long-chain bases in the sphingolipids of [C. lividum] IFO 15163 were identified as dihydro sphingosins (d18:0, d20:1, and d21:1) by gas chromatography-mass spectrometry (data not shown). In the three strains of [A. rhizogenes], octadecenoic acid (18:1) and hexadecenoic acid (16:1) were major nonpolar fatty acids, while in the [C. lividum] strains and the agrobacterium-like isolates, 18:1 fatty acids were the major fatty acids; similarly, small amounts of 16:1 fatty acids were also present, and in agrobacterium-like

* +, positive; w, weakly positive; –, negative.

isolates Y-250T and Y-345T heptadecenoic acids (17:1) were present instead of 16:1 fatty acid. On the other hand, the major 2-hydroxy fatty acid was 2-hydroxymyristic acid (2-OH 14:0) in the five [A. rhizogenes] and [C. lividum] strains. Four of the other five isolates, Y-250T, Y-347T, Y-348, and Y-351, contained 2-hydroxypentadecanoic acid (2-OH 15:0) in addition to the major components 2-OH 14:0, and isolate Y-345T contained 2-OH 15:0 as a major component. No strain contained 3-hydroxy fatty acids. The major component of polyamine was spermidine in the three [A. rhizogenes] strains, the two [C. lividum] strains, and Y-345T and homospermidine in the other isolates.

DNA-DNA homology. As shown in Table 5, the levels of DNA-DNA homology among the three [A. rhizogenes] strains and between the two [C. lividum] strains were 92 to 100 and 86 to 100%, respectively. The levels of homology between the three [A. rhizogenes] strains and all of the other strains tested (Table 5) were less than 28%. The levels of homology between the two [C. lividum] strains and S. yanoikuyae were 62 and 68%. Isolates Y-347T, Y-348, and Y-351 exhibited high levels of
homology (98 to 121%) with each other, but lower levels of
homology with Y-250T (24 to 65%) and Y-345T (57 to 61%).
Similarly, the levels of homology between Y-250T and the other four new isolates and the levels of homology between
Y-345T and the other four new isolates were around 60%.
The levels of homology between the five new isolates and the reference strains (three [A. rhizogenes] strains, one [C. lividum] strain, eight Sphingomonas strains, and one Rhizomonas suberifaciens strain) were less than 36%.

**Phylogenetic analysis.** The sequences of 1372- and 1369
nucleotide fragments of the 16S rDNAs of [A. rhizogenes] IFO 15208 and [C. lividum] IFO 15163, respectively, were determined, and the primary structures were aligned and compared with each other and with the primary structures of 12 reference strains, including strains of Sphingomonas species, *Erthrobacter longus* (18), *Rhizomonas suberifaciens*, *Porphyrobacter neustonensis* (5), and *Roseobacter denitrificans* (17), which are members of the alpha subdivision of the *Proteobacteria* (19, 21, 25). Calculations of levels of sequence similarity were based on the data for 1,244 nucleotides because of deletions. A phylogenetic tree based on $K_{seg}$ values is shown in Fig. 1. As shown in Table 6, the levels of similarity between [A. rhizogenes] and [C. lividum], *Rhizomonas suberifaciens*, and eight strains of Sphingomonas species ranged from 92.8% (S. capsulata) to 95.6% (*Rhizomonas suberifaciens*), while the levels of similarity between [C. lividum] and [A. rhizogenes], *Rhizomonas suberifaciens*, and eight strains of Sphingomonas species ranged from 91.5% (S. capsulata) to 99.4% (*S. yanoikuyae*).

For agrobacterium-like isolates Y-250T, Y-345T, and Y-347T, partial sequences consisting of a 604-bp 16S rDNA fragment extending from nucleotides 227 to 501, 720 to 894, and 1180 to 1383 (E. coli numbering) were determined, and similarity values were calculated on the basis of this 604-bp sequence (Table 7). The levels of similarity between Y-250T

and members of 11 other species, including 8 species of the genus Sphingomonas, Rhizomonas suberifaciens, [A. rhizogenes], and [C. lividum], ranged from 95.7% (S. capsulata) to 100% (isolate Y-347T).

Our 16S rRNA sequence comparison confirmed that [A. rhizogenes], [C. lividum], and isolates Y-250T, Y-345T, and Y-347T all belong to the genus Sphingomonas.

As mentioned above, chemotaxonomic and physiological characteristics and phylogenic data showed that all of the strains which we studied are members of the genus Sphingomonas.

**DISCUSSION**

On the basis of chemotaxonomic and physiological characteristics and the results of DNA-DNA hybridization studies and a 16S rDNA sequence comparison, we propose the following four new species of the genus Sphingomonas: Sphingomonas rosa (type strain, IFO 15208) for the strains isolated from rose plants and formerly named [A. rhizogenes]; Sphingomonas pruni (type strain, IFO 15498) for the strains isolated from Prunus persica; and Sphingomonas asaccharolytica (type strain, IFO 15499) and Sphingomonas mali (type strain, IFO 15500) for the isolates obtained from apple trees. Two strains which were isolated from Psychotria nairobiensis and formerly named [C. lividum] were identified as S. yanoikuyae strains. S. rosa was isolated from the hairy roots of rose plants, but it did not contain either Ti or Ri plasmids and did not exhibit plant pathogenicity (data not shown).

Recently, on the basis of 16S rRNA genes sequencing data, it was found that all of the species belonging to the genera Sphingomonas and Rhizomonas are phylogenetically related and can be divided into several subgroups (13, 24), although it is not appropriate at the present time to transfer these species to other genera, because they have similar chemotaxonomic characteristics and there are no remarkable morphological and physiological differences which distinguish these species at the generic level. We also suggest that the genus Sphingomonas sensu stricto should be restricted to the species S. paucimobilis, S. parapaucimobilis and S. sanguis and that four other species (but not S. capsulata), S. macrogoltabidus, S. terrae, S.

* Data for a 604-bp sequence.
lividum) and S. yanoikuyae strains were less than 70% (62 to 68%). However, these strains shared many chemotaxonomic and physiological features, and the high levels of 16S rDNA similarity (99.8%) between these two taxa support this conclusion. On the other hand, in our phylogenetic study based on a 604-bp 16S rDNA sequence, S. pruni and S. mali exhibited a high level of similarity (100%), but these two organisms could be differentiated by DNA-DNA hybridization data and many physiological characteristics.

Differential characteristics of the new species and of previously described species of the genus Sphingomonas are shown in Table 8. S. pruni does not produce acid from rhamnose and does not assimilate adipate, α-methylglucoside, and raffinose, but S. mali produces acid from rhamnose and assimilates these sugars (Table 2). These organisms also differ in their cellular fatty acid patterns (Table 4).

Strains of four of the species which we studied (S. paucimobilis, S. parapaucimobilis, S. sanguis, and S. yanoikuyae) were found to produce 3-ketolactose from lactose, as shown in Table 8. 3-Ketolactose-forming activity has been found previously only in strains belonging to Agrobacterium biovar 1, and this characteristic has proven to be a useful taxonomic marker for agrobacteria. However, in this study, we found many species of the genus Sphingomonas contain the 3-ketolactose biosynthetic pathway. The results of a study of the distribution of 3-ketolactose-forming activity in members of the alpha subdivision of the Proteobacteria are described in the accompanying paper (15).

The new Sphingomonas species are described below.

### Footnotes
- a The data in parentheses are data for strains IF0 15163 and IF0 15164.
- b +, most strains are positive; -, most strains are negative; w, all strains are weakly positive.
- c See Table 3, footnote a.

The G+C content of the DNA is 64.7 to 65.0 mol%. The major isoprenoid quinone is Q-10. The major nonpolar fatty acids are 16:1, 18:1, and 16:0, and the major 2-hydroxy fatty acid is 2-OH 14:0. Sphingolipid is present. Source: isolated from the hairy roots of Rosa sp. (rose).

The type strain is NCPPB 2661 (= IF0 15208).

### Description of Sphingomonas pruni sp. nov.

**Sphingomonas pruni** (pru'ni. M. L. gen. n. pruni, of Prunus [Prunus persica, peach], the source of the organism) is a gram-negative, nonsporing, motile, rod-shaped organism. Colonies are circular, entire, low convex, smooth, opaque, and light yellow. β-Galactosidase positive. Indole, urease, and arginine dihydrolase are not produced. 3-Ketolactose is produced. β-Galactosidase positive. Deamination of phenylalanine is positive. Gelatin is not liquefied. Reduction of nitrate is weak. Esculin, arabinose, cellobiose, fructose, lactose, maltose, mannose, raffinose, rhamnose, salicin, sucrose, trehalose, and xylose are assimilated, but adonitol, fumarate, malate, malonate, melezitose, sorbitol, starch, and trehalose are not assimilated. Acid is produced from glucose, rhamnose, and salicin but not from glycerol.

The G+C content of the DNA is 64.7 to 65.0 mol%. The major isoprenoid quinone is Q-10. The major nonpolar fatty acids are 16:1, 18:1, and 16:0, and the major 2-hydroxy fatty acid is 2-OH 14:0. Sphingolipid is present. Source: isolated from the hairy roots of Rosa sp. (rose).

The type strain is NCPPB 2661 (= IF0 15208).

### Description of Sphingomonas rosa sp. nov.

**Sphingomonas rosa** (ro'sa. M. L. n. rosa, rose, the source of the organism) is a gram-negative, nonsporing, motile, rod-shaped organism. Colonies are circular, entire, low convex, smooth, opaque, and whitish yellow. Indole, urease, and arginine dihydrolase are not produced. 3-Ketolactose is produced. β-Galactosidase positive. Deamination of phenylalanine is positive. Gelatin is not liquefied. Reduction of nitrate is weak. Esculin, arabinose, cellobiose, fructose, fumarate, galactose, glucuronate, glucose, lactose, maltose, mannose, rhamnose, salicin, sucrose, trehalose, and xylose are assimilated, but adonitol, glyceral, inositol, lactate, malonate, mannitol, raffinose, sorbitol, and tartrate are not assimilated. Acid is produced from glucose weakly, but not from glycerol, rhamnose, and salicin.

The G+C content of the DNA is 65.4 mol%. The major isoprenoid quinone is Q-10. The major nonpolar fatty acids are 17:1, 18:1, 16:0, and the major 2-hydroxy fatty acids are 2-OH 14:0 and 2-OH 15:0. Sphingolipid is present. Source: isolated from the hairy roots of Rosa sp. (rose).
from the roots of Prunus persica (peach) in Tsukuba City, Japan.

The type strain is IFO 15498 (= Y-250).

Description of Sphingomonas asacharolytica sp. nov. Sphingomonas asacharolytica (a.sac.cha.ro.ly'ti.ca. Gr. pref. a., not; Gr. n. sacchar, sugar; Gr. adj. lytica, able to loose: M. L. adj. asacharolytica, not digesting sugar) is a gram-negative, nonsporing, motile, rod-shaped organism. Colonies are circular, entire, low convex, smooth, opaque, and light yellow. β-Galactosidase positive. Indole, urease, and arginine dihydrolase are not produced. Deamination of phenylalanine is negative. 3-Ketolactose is produced. Reduction of nitrate is negative. Gelatin is not liquefied. Esculin, maltose, rhamnose, and xylose are assimilated, but adonitol, cellobiose, fructose, fumarate, galactose, gluconate, glycerol, inositol, lactate, malate, malonate, mannitol, raffinose, salicin, sorbitol, starch, sucrose, and trehalose are not assimilated. Acid is produced from glucose weakly, but not from glycerol, rhamnose, and salicin.

The G+C content of the DNA is 64.8 mol%. The major isoprenoid quinone is Q-10. The major nonpolar fatty acids are 17:1 and 18:1, and the major 2-hydroxy fatty acids are 2-OH 17:1 and 18:1. Sphingolipid is present. Sources: isolated from the roots of Malus spp. (apple) in Tsukuba City, Japan.

The type strain is IFO 15499 (= Y-345).

Description of Sphingomonas mali sp. nov. Sphingomonas mali (mali'. M. L. gen. n. mali, of Malus, the apple genus, the source of the organism) is a gram-negative, nonsporing, motile, rod-shaped organism. Colonies are circular, entire, low convex, smooth, opaque, and light yellow. β-Galactosidase positive. Indole, urease, and arginine dihydrolase are not produced. Deamination of phenylalanine is negative. 3-Ketolactose is produced. Reduction of nitrate is negative. Gelatin is not liquefied. Esculin, cellobiose, fumarate, galactose, gluconate, glycerol, inositol, lactate, malate, malonate, mannitol, raffinose, salicin, sorbitol, starch, sucrose, and trehalose are not assimilated. Acid is produced from glucose weakly, but not from glycerol, rhamnose, and salicin.

The G+C content of the DNA is 64.8 mol%. The major isoprenoid quinone is Q-10. The major nonpolar fatty acids are 17:1 and 18:1, and the major 2-hydroxy fatty acids are 2-OH 17:1 and 18:1. Sphingolipid is present. Sources: isolated from the roots of Malus spp. (apple) in Tsukuba City, Japan.

The type strain is IFO 15500 (= Y-351).

ACKNOWLEDGMENTS

We thank Hiroyuki Sawada, National Institute of Agroenvironmental Sciences, for the plasmid analysis and for the plant pathogenicity tests and Michio Yasuda, Fruit Tree Research Station, Ministry of Agriculture, Forestry and Fisheries of Japan, for providing bacterial strains.
