**Pseudozyma hubeiensis** sp. nov. and **Pseudozyma shanxiensis** sp. nov., novel ustilaginomycetous anamorphic yeast species from plant leaves

Qi-Ming Wang, Jian-Hua Jia and Feng-Yan Bai

Systematic Mycology and Lichenology Laboratory, Institute of Microbiology, Chinese Academy of Sciences, Beijing 100080, China

Among basidiomycetous yeast strains isolated from wilting leaves of various plants in China, two groups of *Pseudozyma* strains were distinguished from the others by morphological and physiological characterization. Molecular taxonomic analysis based on sequencing of the large subunit (26S) rRNA gene D1/D2 domain and internal transcribed spacer (ITS) region confirmed that the two groups represent two novel species. They are proposed as *Pseudozyma hubeiensis* sp. nov. (type strain WS 6.4<sup>T</sup> = AS 2.2493<sup>T</sup> = CBS 10077<sup>T</sup>) and *Pseudozyma shanxiensis* sp. nov. (type strain SH 64<sup>T</sup> = AS 2.2523<sup>T</sup> = CBS 10075<sup>T</sup>). The phylogenetic relationships of the novel species with described *Pseudozyma* species and related ustilagomycetous teleomorphs were analysed based on the combined sequences of ITS and D1/D2. The phenotypic diagnosis of *Pseudozyma* was emended because of the negative inositol assimilation reaction of *P. hubeiensis* sp. nov., which was closely related to the type species of the genus, *Pseudozyma prolifica*.

The anamorphic yeast-like species of *Pseudozyma* belong to the Ustilaginales, as suggested by morphological comparison (Boekhout, 1987) and molecular analysis (Begerow & Bauer, 2000; Boekhout, 1995; Boekhout et al., 1995; Fell et al., 2000). Seven species were included in the genus by Boekhout & Fell (1998). Two more species from the blood of patients were described by Sugita et al. (2003). During a survey of basidiomycetous yeasts living on plant leaves in China, a dozen *Pseudozyma* strains were isolated. Among them, two groups represented by four strains were distinguished from others based on morphological and physiological characterization. Molecular taxonomic analysis based on sequencing of the large subunit (26S) rRNA gene D1/D2 domain and internal transcribed spacer (ITS) region indicated that the two groups represent two novel species.

The strains studied were isolated from wilting plant leaves by using the ballistoconidia-fall method as described by Nakase & Takashima (1993). Strains SH 48 and SH 64<sup>T</sup> were respectively isolated from *Rhododendron oreades* Franch. and *Quercus mongolica* Fisch. ex Ledeb. collected in Taigu, Shanxi Province, and strains WS 4.3.4 and WS 6.4<sup>T</sup> were respectively isolated from *Litsea* sp. and *Magnolia denudata* Desr. collected in Wuhan, Hubei Province.

Most of the morphological, physiological and biochemical characteristics were examined according to standard methods (Yarrow, 1998). Extraction, purification and identification of ubiquinones were carried out according to Yamada & Kondo (1973). Assimilation of nitrogen compounds was investigated on solid media with starved inocula (Nakase & Suzuki, 1986).

Nuclear DNA was extracted by using the method of Makimura et al. (1994). Sequences of the ITS (including the 5S rRNA gene) and the 26 rRNA gene D1/D2 domain were determined by methods described previously (Bai et al., 2002). Sequences were aligned with the CLUSTAL X program (Thompson et al., 1997). Phylogenetic trees were constructed from evolutionary distance data calculated from Kimura’s two-parameter model (Kimura, 1980) by using the neighbour-joining method (Saitou & Nei, 1987). Bootstrap analyses (Felsenstein, 1985) were performed from 1000 random resamplings.

**Phenotypic characterization**

Though strains SH 48, SH 64<sup>T</sup>, WS 4.3.4 and WS 6.4<sup>T</sup> were isolated by a method for selective isolation of ballistoconidium-forming yeasts, they did not form forcibly discharged conidia on agar plates. The non-ballistoconidium-forming yeast strains that were frequently isolated using this method usually belonged to *Rhodotorula* or *Cryptococcus*. However, the morphological characters of the four strains studied were not typical of these two genera. The positive diazonium blue B and urease reactions showed their basidiomycetous nature. They did not

**Abbreviation:** ITS, internal transcribed spacer.

The GenBank/EMBL/DDBJ accession numbers for the ITS region sequences of strains WS 6.4<sup>T</sup> and SH 64<sup>T</sup> are DQ008954 and DQ008956 and those for the 26S rRNA gene D1/D2 domain sequences are DQ008953 and DQ008955, respectively.

produce extracellular starch-like compounds and their major ubiquinone was Q-10. On agar media, they formed yeast-like colonies with pseudohyphae at the margin and produced fusiform blastoconidia by budding on short sterigma-like stalks. Sexual structures were not observed in cultures of single strains or in mating tests. The characteristic colony and blastoconidium morphology suggest that they belong to the genus *Pseudozyma* as defined by Boekhout (1995) and Boekhout & Fell (1998). The four strains can be classified into two groups by morphological characters. Strains WS 4.3.4 and WS 6.4T form whitish colonies and predominantly cylindrical cells, whereas strains SH 48 and SH 64T formed brownish-yellow colonies and predominantly apiculate cells.

**Sequence analysis**

The two groups represented by SH 64T and WS 6.4T recognized from morphological characterization were confirmed by D1/D2 and ITS sequence comparison. The strains within each of the two groups have identical D1/D2 and ITS sequences. They were clustered in the Ustilaginales clade as defined by Begerow & Bauer (2000) and Fell et al. (2000) in the tree drawn from D1/D2 sequences (data not shown). The sequence analysis confirmed the assignment of the strains studied to the genus *Pseudozyma*. Within this genus, SH 64T and WS 6.4T were most closely related to *Pseudozyma fusiformata* and *Pseudozyma prolifica*, respectively. Strain SH 64T differed from *P. fusiformata* by 9 (1.5%) substitutions in the D1/D2 regions and more than 20% mismatches in the ITS region. Strain WS 6.4T differed from *P. prolifica* by 11 (1.9%) substitutions in the D1/D2 region and more than 10% mismatches in the ITS region. The sequence comparison indicated that strains SH 64T and WS 6.4T represent two novel *Pseudozyma* species, for which the names *Pseudozyma shanxiensis* sp. nov. and *Pseudozyma hubeiensis* sp. nov. are proposed.

The phylogenetic relationships of the novel species with described *Pseudozyma* species and related teleomorphs of the Ustilaginales were further analysed based on the combined sequences of the ITS and D1/D2 regions (Fig. 1). Selection of the reference teleomorphs was based on Begerow & Bauer (2000) and Stoll et al. (2005).

*P. shanxiensis* sp. nov. was located in the *Ustilago sensu stricto* group of the *Ustilago sensu lato* clade (Stoll et al., Fig. 1. Phylogenetic tree drawn from neighbour-joining analysis of the combined sequences of the ITS region (including the 5.8S rRNA gene) and the 26S rRNA gene D1/D2 domain, depicting the relationships of the two novel *Pseudozyma* species with described species of the genus and related ustilagomycetous teleomorphs. *Rhodotorula acheniorum* is designated the outgroup. Lines ending in dots indicate the positions of *Pseudozyma* species. Bootstrap percentages over 50% from 1000 bootstrap replicates are shown. Reference sequences were retrieved from GenBank under the accession numbers indicated; single accession numbers represent sequences that cover both regions.
The closest teleomorphic relatives of this species were *Ustilago striiformis* and *Ustilago calamagrostidis* (Fig. 1). The latter two species differed from each other by only one substitution in each of D1/D2 and ITS regions, implying their conspecificity, as pointed out by Stoll et al. (2005). *P. shanxiensis* sp. nov. differed from the latter two by 2–3 substitutions in the D1/D2 region and 18 substitutions and 12 indels in the ITS region, suggesting that the novel species may not be the anamorph of the *Ustilago* species. *P. fusiformata* was located on a basal branch of this group.

*P. hubeiensis* sp. nov. and the type species of the genus, *P. prolifica*, were clustered in the *Ustilago maydis* group of the *Sporisorium* clade (Stoll et al., 2005). *P. hubeiensis* sp. nov. was most closely related to *Sporisorium trachypogonis-plumosi* and the latter two species by 10–11 substitutions in the ITS region, suggesting that the novel species may not be the anamorph of the *Ustilago* species. *P. fusiformata* was located on a basal branch of this group.

The remaining species of *Pseudozyma* were clustered in other different groups with different ustilaginomycetous teleomorphs (Fig. 1). *Pseudozyma tsukubaensis* and *Pseudozyma thailandica* were closely related with the species in the *Ustilago–Sporisorium* clade of Stoll et al. (2005). The anamorph–teleomorph relationship between *P. tsukubaensis* and *Ustilago spermophora* suggested by Begerow & Bauer (2000) based on D1/D2 sequences was supported by ITS sequence comparison in the present study. They differed by only 1 substitution in this region. *Pseudozyma graminicola*, which has not been formally described, and *Pseudozyma flocculosa* are located in the *Sporisorium 1* and *Sporisorium 2* groups, respectively, of the *Sporisorium* clade (Stoll et al., 2005). The four other *Pseudozyma* species formed a well-supported clade together with *Moeszioniomyces bullatus* and *Macalpinomyces eriachnes* (Fig. 1).

**Emendation of the diagnosis of Pseudozyma**

According to the current definition of *Pseudozyma*, one of the diagnostic phenotypic criteria of the genus is the positive reaction for assimilation of inositol (Boekhout & Fell, 1998). However, the two strains of *P. hubeiensis* sp. nov. can not assimilate this compound. Phylogenetically, *P. hubeiensis* sp. nov. is more closely related to the type species *P. prolifica* than to the other described species of the genus. Therefore, the positive inositol assimilation reaction should be deleted from the diagnosis of the genus.

**Latin diagnosis of Pseudozyma hubeiensis Bai & Wang sp. nov.**

In YM broth, after 5 days at 20 °C, cells are mostly cendrical, 2.0–3.7 × 5.0–10.0 μm (Fig. 2a), single or in pairs. Budding is polar on short stalks. Sediment, a ring and a pellicle are formed. After 1 month at 20 °C, sediment, a ring and a pellicle are present. On YM agar, after 1 month at 20 °C, the streak culture is whitish to cream, butyrous, dull, smooth or somewhat wrinkled. The margin is entire or somewhat eroded. In Dalmau plate culture on cornmeal agar, pseudohyphae are formed. Fermentation of glucose is negative. Glucose, galactose, sucrose, maltose, cellobiose, trehalose, lactose, melibiose, raffinose, melezitose, soluble starch (delayed and weak), D-xyllose, L-arabinose, D-ribose, D-glucosamine, glycerol, erythritol, ribitol, D-mannitol, D-glucitol, methyl D-xylosidur, succinic acid and hexadecane are assimilated. L-Sorbose, inulin, L-rhamnose, methanol, ethanol, galactitol, salicin, D-lactic acid, citric acid and inositol are not assimilated. Ammonium sulfate, potassium nitrate, sodium nitrite, L-lysine, ethylamine hydrochloride and cadaverine dihydrochloride are all assimilated. Maximum growth temperature is 36–37 °C. Growth in vitamin-free medium is positive. Starch-like substances are not produced. Growth on 50 % (w/w) glucose/yeast extract agar is negative. Urease activity is positive. Diazonium blue B reaction is positive. The major ubiquinone is Q-10.

The type strain, WS 6.4T, was isolated from a wilting leaf of *Magnolia denudata* Desr. collected in Hubei Province, China, in July 2002. This strain has been deposited in the China General Microbiological Culture Collection Center, China General Microbiological Culture Collection Center.
(CGMCC), Academia Sinica, Beijing, China, as AS 2.2493T (=CBS 10077T).

Latin diagnosis of *Pseudozyma shanxiensis* Bai & Wang sp. nov.

Description of *Pseudozyma shanxiensis* Bai & Wang sp. nov.

*Pseudozyma shanxiensis* (shan.xi.en’sis. N.L. fem. adj. *shanxiensis* of Shanxi, referring to the geographical origin of the type strain).

In YM broth, after 5 days at 20 °C, cells are fusiform or cylindrical, 1·5–3·0 × 5·2–10·0 μm (Fig. 2b), single or in pairs. Budding is polar on short stalks. Sediment and a ring are formed. After 1 month at 20 °C, sediment, a ring and a pellicle are present. On YM agar, after 1 month at 20 °C, the streak culture is brownish-yellow or brownish, butyrous, dull and wrinkled. The margin is eroded. In Dalma plate culture on cornmeal agar, pseudohyphae are formed. Fermentation of glucose is negative. Glucose, galactose, sucrose, maltose, trehalose (or weak), lactose, melibiose,

**Fig. 2.** Vegetative cells of *Pseudozyma hubeiensis* sp. nov. WS 6.4T (a) and *Pseudozyma shanxiensis* sp. nov. SH 64T (b) grown in YM broth for 5 days at 20 °C. Bars, 10 μm.
raffinose, melezitose, soluble starch (or weak), D-xylene, L-arabinose, D-arabinose (variable), D-ribose (variable), ethanol, glycerol, D-mannitol (or weak), D-glucitol (or weak), methylv-2-D-glucoside, salicin (variable), succinic acid, inositol (weak) and hexadecane are assimilated. L-Sorbose (or delayed and weak), cellobiose, inulin (or weak), L-rhamnose, D-glucosamine (or delayed and weak), methanol, erythritol, ribitol (or delayed and weak), galactitol, DL-lactic acid (or delayed and weak) and citric acid (or delayed and weak) are not assimilated. Ammonium sulfate, potassium nitrate, sodium nitrite, L-lysine, ethylamine hydrochloride and cadaverine dihydrochloride are all assimilated. Maximum growth temperature is 40–41°C. Growth in vitamin-free medium is positive. Starch-like substances are not produced. Growth on 50 % (w/w) glucose/yeast extract agar is negative. Urease activity is positive. Diazonium blue B reaction is positive. The major ubiquinone is Q-10.

The type strain, SH 64T, was isolated from a wilting leaf of Quercus mongolica Fisch. ex Ledeb. collected in Shanxi Province, China, in July 2001. This strain has been deposited in the CGMCC, Academia Sinica, Beijing, China, as AS 2.2523T ( = CBS 10075T).

Identification

In practice, P. hubeiensis sp. nov. differs from the other species of the genus by its inability to assimilate inositol. P. shanxiensis sp. nov. can be differentiated from the other species of the genus by the assimilation reactions for erythritol, lactose, L-rhamnose and ethanol and the ability to grow at 40 °C (Table 1).
