²CHU de Montpellier, Laboratoire de Bactériologie, Hôpital Arnaud de Villeneuve, 371 Avenue du doyen Gaston Giraud, F-34295 Montpellier Cedex 5, France

Three novel Gram-negative, non-fermenting aerobic bacilli were isolated from human clinical samples. They shared more than 99.8 % of the 16S rRNA gene nucleotide positions. The strains were related to Ochrobactrum intermedium with about 97.48 % 16S rRNA gene sequence similarity. In 16S rRNA gene-, dnaK- and rpoB-based phylogenies, the strains were grouped in a lineage that was distinct from other Ochrobactrum species in the family Brucellaceae. Fatty acid composition, polar lipids, quinone system, DNA–DNA relatedness, genome organization, and physiological and biochemical data differentiated these isolates from recognized species of the genus Ochrobactrum. The three clinical strains therefore represent a novel species within the genus Ochrobactrum, for which the name Ochrobactrum pseudintermedium sp. nov., is proposed. The type strain is ADV31T (=CIP 109116T = DSM 17490T). The DNA G + C content of strain ADV31T was 54.5 mol%.

The genus Ochrobactrum belongs to the family Brucellaceae in the class Alphaproteobacteria. It currently comprises seven species that were isolated from a wide variety of environmental sources (soil, rhizosphere) (Lebuhn et al., 2000), as well as from plants (Trujillo et al., 2005; Tripathi et al., 2006), animals (Kämpfer et al., 2003) and humans (Holmes et al., 1988; Velasco et al., 1998). To date, Ochrobactrum anthropi and Ochrobactrum intermedium are the only species to be recovered from human clinical samples (Teyssier et al., 2005a). In this study, we characterized three strains of an Ochrobactrum sp. that were isolated from two patients hospitalized in intensive-care units of the Montpellier University Hospital, France. We used genetic, phylogenetic, genomic and phenotypic analyses to compare these strains with known Ochrobactrum species. This study led to the description of a novel species in the genus Ochrobactrum.

The three isolates were recovered from samples taken during the standard procedure for the detection of multi-resistant bacilli carriage in patients hospitalized in intensive-care units. The strains grew after incubation for 24–48 h at 37 °C on Drigalski agar (Difco), supplemented with 4 mg ceftazidime L⁻¹, a medium that is selective for multi-resistant, non-exigent, Gram-negative bacteria. Strain ADV31T was isolated in 2002 from an axillary swab from a 20-year-old man. Isolates ADV41 and ADV43 were recovered in 2003 from rectal swabs taken 48 h apart from a 25-year-old man hospitalized in a different intensive-care unit. PFGE of SpeI-restricted DNA performed as described previously (Teyssier et al., 2003a) showed that strains ADV41 and ADV43 were not related (data not shown).

Genomic DNA used for PCR was obtained using an AquaPure genomic DNA isolation kit (Bio-Rad). Amplification of the 16S rRNA gene was performed using the universal primers 27f and 1492r (Teyssier et al., 2003a) or primers F4 and R2 that are described as being specific for Brucella spp. and O. intermedium (Romero et al., 1995; Velasco et al., 1998). Partial dnaK (encoding the 70 kDa heat-shock protein) and rpoB (encoding the DNA-dependent RNA polymerase β-subunit) gene amplifications

The GenBank/EMBL/DDBJ accession numbers for the 16S rRNA, dnaK and rpoB gene sequences of strain ADV31T are DQ365921, DQ393570 and DQ926698, respectively; those for strain ADV41 are DQ365922, DQ393571 and DQ926699, respectively; and those for strain ADV43 are DQ393572 and DQ926700, respectively.

A phylogenetic tree based on concatenated dnaK and rpoB gene sequences of strains ADV31T, AD41 and AD43 and other members of the genera Ochrobactrum and Brucella, a schematic representation of the rrs skeleton of the two chromosomes of strain ADV31T and a two-dimensional thin-layer chromatogram of the polar lipids of strain ADV31T are available as supplementary figures in IUSEM Online.

On: Tue, 11 Dec 2018 18:07:46
were carried out with primers 289f (5'-ATCGTCAAGG-GCGACAATGGC-3')/1142r (5'-CGTCCTTGACGTCGC-CCTGCA-3') and 453f (5'-ATCGTTTCGCAGATGCAC-CG-3')/1232r (5'-CGCATGTTCATCTTCACGCGGCC-3'), respectively. The PCR reactions were all performed as described previously for 16S rRNA gene amplification (Teyssier et al., 2003a). Sequencing was done in both directions with forward and reverse primers using an Applied Biosystems Automatic Sequencer (Genome Express). Partial 16S rRNA gene sequences of about 1400 bp were compared with sequences deposited in GenBank/EMBL/DDBJ using the standard BLAST program (www.ncbi.nlm.nih.gov/blast) and LALIGN software (www.expasy.org). The three isolates, ADV31T, ADV41 and ADV43, shared more than 99.8% of their nucleotide positions. The highest 16S rRNA gene sequence similarity was obtained with the type strain of O. intermedium (97.48%). However, PCR using primers F4 and R2 was negative for strains ADV31T, ADV41 and ADV43, clearly differentiating these strains from O. intermedium (Velasco et al., 1998). The dnaK and rpoB sequences also distinguished strain ADV31T from other members of the genus Ochrobactrum, as the maximum similarity levels were 95.5% with O. intermedium for dnaK and 93.6% with O. anthropi for rpoB. The similarity levels among strains ADV31T, ADV41 and ADV43 were greater than 98.9 and 97.5% for dnaK and rpoB, respectively. 16S rRNA gene-, dnaK- and rpoB-based phylogenies were used to analyse the relationships between the three clinical isolates and members of the genera Ochrobactrum and Brucella. A single dnaK- and rpoB-based tree was reconstructed using a concatenation of dnaK and rpoB sequences. A distance matrix was calculated using the F84 algorithm (Kishino & Hasegawa, 1989) in the DNADIST program after sequence alignment with CLUSTAL_X (Thompson et al., 1997). The neighbour-joining method (Saitou & Nei, 1987) was used to reconstruct distance trees. The results were compared with trees obtained using parsimony (Kluge & Farris, 1969) and maximum-likelihood (Olsen et al., 1994) with the programs DNAPARS and fastDNAm1, respectively. The robustness of the trees was evaluated by bootstrap analysis of 1000 replicates using the programs SEQBOOT and CONSENSE. All the phylogenetic programs used were from PHYLIP package 3.66 (Felsenstein, 1993). Independent of methods and markers, strains ADV31T, ADV41 and ADV43 were grouped in a lineage that was distinct from other species of the genus Ochrobactrum and supported by high bootstrap values (Fig. 1 and Supplementary Fig. S1 in IJSEM Online). The phylogenetic analysis showed that isolates ADV31T, ADV41 and ADV43 should be considered as representing a novel species in the genus Ochrobactrum. Independent lineages, each corresponding to a single Ochrobactrum species, were observed in all the trees reconstructed, except for Ochrobactrum lupini, which formed a monophyletic group with O. anthropi ATCC 49188T (Fig. 1 and Supplementary Fig. S1 in IJSEM Online). The phylogenetic analysis showed that isolates ADV31T, ADV41 and ADV43 should be considered as representing a novel species in the genus Ochrobactrum. Independent lineages, each corresponding to a single Ochrobactrum species, were observed in all the trees reconstructed, except for Ochrobactrum lupini, which formed a monophyletic group with O. anthropi ATCC 49188T (Fig. 1 and Supplementary Fig. S1 in IJSEM Online).
Supplementary Fig. S1 in IJSEM Online). The relative branching of \(O. \text{intermedium}\) and \(Ochrobactrum \) grignonense differed between 16S rRNA- and \(dnak-rpoB\)-based trees. The\(\text{dnak-rpoB}\)-based tree displayed higher bootstrap values than those obtained in the 16S rRNA gene-based tree. This confirmed that the evolutionary relationships among members of the genus \(Ochrobactrum\) cannot be resolved using the 16S rRNA gene alone. In addition to recA (Scholz et al., 2006), the two markers proposed herein are useful for studying species diversity in the genus \(Ochrobactrum\). Additional comparative sequence analysis showed that 16S rRNA gene sequences deposited in databases for strains that have not been identified to the species level matched the sequences of the clinical isolates studied. These sequences were used to reconstruct a 16S rRNA gene-based tree (data not shown). The tree showed that \(Ochrobactrum\) strain CGL-X (GenBank accession no. DQ305290) might represent another member of the novel species, as well as strain TKW2 (AY631061) deposited as \(Rhzobium\) sp. and strain YBJCA-1 (DQ305284) deposited as \(Brucella\) sp.

Strains ADV31\(^T\), ADV41 and ADV43 were compared with the type strains of other \(Ochrobactrum\) species: \(O. \text{anthropi}\) ATCC 49188\(^T\), \(O. \text{intermedium}\) LMG 3301\(^T\), \(O. \text{grignonense}\) DSM 13338\(^T\), \(Ochrobactrum \) tritici DSM 13340\(^T\), \(Ochrobactrum \) gallinifaces DSM 15295\(^T\) and \(O. \text{lupini}\) LMG 22726\(^T\). Data from the literature were used to compare the three strains with the recently described species \(Ochrobactrum \) oryzae (Tripathi et al., 2006).

DNA–DNA hybridization between \(O. \text{intermedium}\) LMG 3301\(^T\) and strain ADV31\(^T\) was performed, according to the methods of De Ley et al. (1970) with the modifications of Huß et al. (1983), at the Identification Service of the Deutsche Sammlung von Mikroorganismen und Zellkulturen (DSMZ; Germany). The values obtained in duplicate experiments were 37.7 and 48.2\%, confirming that isolate ADV31\(^T\) does not belong to the species \(O. \text{intermedium}\). The DNA G + C content of strain ADV31\(^T\), determined by HPLC (Mesbah et al., 1989), was 54.5 mol\%, a value that was different from those reported for other members of the genus \(Ochrobactrum\) (Table 1).

Intact genomic DNA of strains ADV31\(^T\), ADV41 and ADV43 was subjected to PFGE in order to count and size large replicons (Teyssier et al., 2005b). The \(rrn\) skeleton was constructed as described previously (Teyssier et al., 2003b, 2005b). The genomes of the three clinical strains harboured two circular chromosomes of about 2.8 and 1.78 Mb. In addition, strain ADV31\(^T\) possessed a plasmid of 0.44 Mb. \(I-Ce\)l digestion led to four restriction fragments, indicating the presence of four \(rrn\) copies in the genome of the three strains. Two \(rrn\) copies were located on each chromosome (see Supplementary Fig. S2 in IJSEM Online). These results were in agreement with the affiliation of the isolates to the genus \(Ochrobactrum\). Indeed, the bipartite organization of the genome and the \(rrn\) skeleton of the large chromosome have been described previously as being characteristic of this genus (Teyssier et al., 2005b). The \(rrn\) organization of the small chromosome was identical to that of \(O. \text{anthropi}\), \(O. \) grignonense, \(O. \) tritici and \(O. \) lupini, but was different from that of \(O. \text{intermedium}\) and \(O. \) gallinifaces (Teyssier et al., 2005b).

Cells of strains ADV31\(^T\), ADV41 and ADV43 were Gram-negative, straight or slightly curved short rods, with one flame-shaped end. The cells appeared to be motile under microscopic observation and after culture on mannitol motility nitrate broth medium (Bio-Rad). Electron microscopy after negative staining, performed as described previously (Marchand et al., 2003) and observed with a Hitachi H7100 electron microscope, showed the presence of one or two flagella in a subterminal position. Cells were 0.65–0.75 × 1.5–1.7 \(\mu\)m in size. The strains were cultivated on tryptic soy agar (Difco) at 25, 30, 37 and 45 °C. Colonies were non-pigmented, mucoid and opaque. The three strains grew on MacConkey medium (Difco) only at 37 °C and did not grow on cetrimid agar (Difco), independent of the incubation temperature. General metabolic characteristics were common to those of all members of the genus \(Ochrobactrum\); aerobic respiration, presence of catalase and cytochrome oxidase, oxidative metabolism and acids not being produced from carbohydrates on the API 20E system (bioMérieux). Eighty-one biochemical characteristics were determined using the API 20E and API 20NE systems and VITEK 2 with ID-GN card version WSVT2-R04.01 (bioMérieux), according to the manufacturer’s instructions. A comparison of the data obtained for strains ADV31\(^T\), ADV41 and ADV43 and those for the type strains of other \(Ochrobactrum\) species is given in Table 1. The antimicrobial susceptibility pattern was determined by using the disc-diffusion assay on Mueller–Hinton agar, according to the recommendations of the SFM antibiogram committee for Gram-negative non-fermenters (Members of the SFM Antiibiogram Committee, 2003). Antibiotic susceptibility patterns for strains ADV31\(^T\), ADV41 and ADV43 and other \(Ochrobactrum\) species are compared in Table 1. As generally observed for the genus \(Ochrobactrum\), the three isolates were resistant to all β-lactams except imipenem (10 \(\mu\)g) (Teyssier et al., 2005a). They were also resistant to colistin (50 \(\mu\)g) and susceptible to tobramycin (10 \(\mu\)g) and netilmicin (30 \(\mu\)g). This pattern differentiated strains ADV31\(^T\), ADV41 and ADV43 from the two other \(Ochrobactrum\) species recovered from human clinical samples (Teyssier et al., 2005a). Indeed, \(O. \text{anthropi}\) strains were susceptible to colistin, tobramycin and netilmicin, whereas \(O. \) intermedium strains were resistant to these three antibiotics (Teyssier et al., 2005a). Moreover, strains ADV31\(^T\), ADV41 and ADV43 were resistant to tetracycline (30 \(\mu\)g), unlike other \(Ochrobactrum\) species.

Chemotaxonomic analyses of strain ADV31\(^T\), including fatty acid methyl esters, respiratory quinones and polar lipids, were performed at the Identification Service of the DSMZ, according to Tindall (1990a, b) and Kämpfer et al. (1994). Predominant cellular fatty acids were \(C_{19:0}\) w8c and \(C_{18:1}\) o7c, constituting 39.8 and 29.3 of the total fatty acid methyl esters, respectively. Other fatty acids were

present at moderate or low amounts (Table 2). This profile was most similar to that of O. gallinifaecis, but differed from those of the type strains of other Ochrobactrum species (Kämpfer et al., 2003; Tripathi et al., 2005). Two respiratory lipoquinones, ubiquinone 10 and ubiquinone 9, were detected, at peak area ratios of 96 and 4%, respectively. The presence of ubiquinone 10 as the dominant respiratory lipoquinone is characteristic of members of the Alphaproteobacteria (Lechner et al., 1995). The major polar lipids were phosphatidylglycerol, phosphatidyethanolamine and phosphatidylcholine. In addition, diphosphatidylglycerol, aminophospholipid and an unidentified aminolipid were detected in moderate amounts (see Supplementary Fig. S3 in IJSEM Online).

*Data obtained using VITEK 2 with ID-GN card (bioMérieux).
†Data obtained using 20E and 20NE API systems (bioMérieux) after 48 h of incubation.
‡Data for API systems and antibiotic susceptibility are from Teissier et al. (2005a).
§Other β-lactams: aztreonam (30 μg), cefalotin (30 μg), cefepime (30 μg), cefotaxime (30 μg), ceftiraxone (30 μg), ceftazidime (30 μg), imipenem (10 μg), piperacillin (75 μg), piperacillin/tazobactam (75 μg/10 μg), ticarcillin (75 μg), ticarcillin/clavulanic acid (75 μg/10 μg).
¶All strains are susceptible to imipenem and resistant to aztreonam.
¥Data from: a, Velasco et al. (1998); b, Holmes et al. (1988); c, Lebuhn et al. (2000); d, Trujillo et al. (2005).

The unidentified aminophospholipid in the profile of strain ADV31 was most similar to that of O. gallinifaecis, but differed from those of the type strains of other Ochrobactrum species (Kämpfer et al., 2003; Tripathi et al., 2005). Consequently, we could not show any obvious differences between the polar lipid profiles of strain ADV31 and O. gallinifaecis.

Some characteristics that are useful for the routine identification of Ochrobactrum spp. (Teissier et al., 2005a) were common to strains ADV31, ADV41 and ADV43 and O. intermedium (mucoid colonies, ability to grow on tryptic soy agar at 45°C, absence of urease activity and resistance to colistin). In addition, genotyping and phylogeny showed that the novel species was related to O. intermedium, supporting its denomination as Ochrobactrum pseudointermedium sp. nov. However, the 16S rRNA gene-, dnaK- and rpoB-phylogenies, DNA–DNA hybridization, G + C content, rrr skeleton of the small chromosome, PCR specific for Brucella spp. and O. intermedium, phenotype and chemotaxonomy clearly differentiated strains ADV31, ADV41 and ADV43 from O. intermedium. Together, the results support the creation of a novel species to accommodate isolates ADV31, ADV41 and ADV43 and its denomination as Ochrobactrum pseudointermedium sp. nov. is proposed.

**Description of Ochrobactrum pseudointermedium sp. nov.**

Ochrobactrum pseudointermedium (pseud.in’ter.med’i.um. Gr. adj. pseudo=false; L. neut. adj. intermedium intermediate, and a specific epithet of the genus Ochrobactrum; N.L. neut. adj. pseudointermedium a false Ochrobactrum intermedium).

Cells are Gram-negative, non-spore forming, short rods, and motile by subpolar flagella. Cells are 0.65–0.75 × 1.5–1.7 μm in size. Growth occurs at 25–45°C on tryptic soy agar. Grows on MacConkey agar and R2A agar at 37°C. Colonies are non-pigmented, mucoid and opaque. Aerobic respiration, oxidative metabolism, nitrate reduction and catalase and oxidase are positive. Positive for glycine arylamidase, L-proline arylamidase, tyrosine arylamidase and L-tryptophan arylamidase activities, assimilation of glucose, arabinose, mannose, maltose, potassium gluconate, D-mannitol, N-acetylgalactosamine, D-maltose and capric acid, acidification of adonitol and D-tagatose, and alkalization of L-lactate and succinate. Negative for activities of DNase, urease, phenylalanine deaminase, tryptophan deaminase, Glu-Gly-Arg arylamidase and β-alanine arylamidase p-nitroanilide (pNA), arginine dihydrolase, Ala-Phe-Pro arylamidase, glutamyl arylamidase pNA,
β-xyllosidase, lipase, N-acetyl-β-galactosaminidase, α-galactosidase, β-galactosidase (ONPG), N-acetyl-β-glucosaminidase, phosphorylase, ornithine decarboxylase, lysine decarboxylase, β-glucuronidase and β-glucosidase (aesculin hydrolysis). Negative for acidification of D-glucose, D-mannose, L-arabitol, D-cellobiose, D-mannitol, D-trehalose, malonate, 5-keto-D-gluconate and coumarate, production of indole, acetoin and H$_2$S, hydrolysis of gelatin, assimilation of adipic acid, phenylacetic acid, L-histidine and L-lactate, and fermentation of carbohydrates. Resistant to β-lactams except imipenem, and to chloramphenicol, tetracycline, fosfomycin and colistin. Susceptible to aminoglycosides (gentamicin, tobramycin, netilmicin, isepamicin, amikacin), fluoroquinolones (pefloxacin, ofloxacin, ciprofloxacin), nalidixic acid, rifampicin and trimethoprim-sulfamethoxazole. Major fatty acids are C$_{19}$ : 0 cyclo o8c and C$_{18}$ : 0 10c. Ubiquinone 10 is the dominant respiratory lipoquinone. Polar lipids mainly comprise phosphatidylglycerol, phosphatidylethanolamine and phosphatidylcholine. 16S rRNA gene amplification is not obtained with primers F4 and R2 (Velasco et al., 1998). Genome is constituted of two chromosomes of about 2.8 and 1.8 Mb comprising four rrr copies with two rrn operons in divergent orientation on the small chromosome. The G+C content of the DNA of the type strain is 54.5 mol%. Can be differentiated from other species of the genus Ochrobactrum by 16S rRNA, dnaK and rpoB gene sequencing.

The type strain is ADV31$^T$ (≡ CIP 109116$^T$=DSM 17490$^T$), which was isolated from a human clinical sample.

Acknowledgements

We gratefully acknowledge Bernard Gay for electron microscopy ‘observations’. We also wish to thank Isabelle Zorgniotti and Jean-Luc Jeannot for excellent technical assistance. This work is partly supported by the association ADEREMPHA (Montpellier France).
