3DSMZ-Deutsche Sammlung von Mikroorganismen und Zellkulturen GmbH, Inhoffenstraße 7b, 38124 Braunschweig, Germany

A yellow-pigmented, Gram-negative, aerobic bacterial strain, designated 5YN10-9T, was isolated from a wetland, Yongneup, of the Inje region, Korea. Cells were motile by means of one polar flagellum. Based on 16S rRNA gene sequence analyses, strain 5YN10-9T was shown to be related to the genera *Azoarcus*, *Azovibrio*, *Thauera* and *Zoogloea*, showing moderate sequence similarities of 90.2–93.3, 92.7, 90.9–93.3 and 92.4–92.6 % to members of these genera, respectively. Its distinct phylogenetic position and the low 16S rRNA gene sequence similarity values toward the closest related genera support the inclusion of this novel isolate in a new genus. The major isoprenoid quinone was ubiquinone 8 (Q-8). The predominant cellular fatty acids were C16:0 and summed feature 3 (comprising C16:1ω7c and/or iso-C15:0 2-OH). The DNA G+C content was 59.3 mol%. The results of phenotypic, chemotaxonomic and phylogenetic analyses indicate that strain 5YN10-9T represents a novel species of a new genus within the family *Rhodocyclaceae*, class *Betaproteobacteria*, for which the name *Uliginosibacterium gangwonense* gen. nov., sp. nov. is proposed. The type strain is 5YN10-9T (≡KACC 11603T=DSM 18521T).

Garrity & Holt (2001) listed five genera, *Rhodococcus*, *Azoarcus*, *Propionibacter*, *Thauera* and *Zoogloea*, within the family *Rhodocyclaceae*. Since then, many genera, for example *Azonexus*, *Azospira*, *Azovibrio* (Reinhold-Hurek & Hurek, 2000), *Dechloromonas* (Achenbach et al. 2001), *Ferrribacterium* (Cummings et al., 1999), *Propionivibrio* (Brune et al., 2002), *Quadricoccus* (Maszenan et al., 2002) and *Sterolibacterium* (Tarlera & Denner, 2003), have been newly classified within the family *Rhodocyclaceae*, class *Betaproteobacteria* (Garrity et al., 2005). The type genus of the family *Rhodocyclaceae* is *Rhodococcus*.

Yongneup (38°12′53″ N 128°07′30″ E) is a wetland located at over 1200 m above sea level and is the only high moor in Korea. Peat layers in the wetland are about 150 cm thick and have been formed over the past 4000–5000 years. Wetland peat samples were serially diluted with 0.85 % NaCl (w/v) and suitable ten-fold dilutions were plated onto R2A agar (Difco). These plates were incubated at 28 °C for 4 days. Among the colonies subsequently formed, a yellow-coloured colony was isolated and designated 5YN10-9T. This isolate was able to grow on R2A and nutrient agar (NA; Difco), but not on trypticase soy agar (TSA; Difco) or MacConkey agar (Difco).

Cell morphology was observed by transmission electron microscopy (912AB; LEO) and phase-contrast microscopy (AXIO; Zeiss) by using cells grown on R2A agar. The pH, temperature and NaCl ranges for growth were determined by using R2A medium. Strain 5YN10-9T was analysed phenotypically by using the API 20NE, API ZYM and API ID 32 GN systems (bioMérieux) according to the manufacturer’s instructions. Gram staining, presence of catalase, oxidase, poly-β-hydroxybutyrate, and hydrolysis of casein, DNA and starch were determined as described by Smibert & Krieg (1994). Hydrolysis of carboxymethyl-cellulose (CM-cellulose; Sigma) (0.1 %, w/v), chitin from crab shells (1 %, w/v), pectin (0.5 %, w/v) and tyrosine (0.5 %, w/v) was also tested. Cells of strain 5YN10-9T were Gram-negative, motile by means of a single, polar flagellum, rod-shaped and strictly aerobic (Fig. 1). Table 1 lists the phenotypic differences between strain 5YN10-9,T and other closely related genera.

The procedure for identification of isoprenoid quinones followed the HPLC method of Groth et al. (1996). DNA G+C content was determined by HPLC analysis of deoxyribonucleosides as described by Mesbah et al. (1989). The GenBank/EMBL/DDBJ accession number for the 16S rRNA gene sequence of strain 5YN10-9T is DQ665916.
(1989), by using a reversed-phase column (Supelcosil LC-18 S; Supelco). Analysis of fatty acid methyl esters was carried out according to the standard protocol of the Sherlock Microbial Identification System (Sasser, 1990). Strain 5YN10-9T had ubiquinone 8 as the predominant isoprenoid quinone. The DNA G+C content was 59.3 mol%. Strain 5YN10-9T contained C16:0 (35.2 %) and summed feature 3 (comprising C16:1ω7c and/or iso-C15:0 2-OH; 28.5 %) as the predominant cellular fatty acids. The following components were also present at >1% of the total fatty acids (Table 2): C18:1ω7c (7.4 %), C17:0 cyclo (5.9 %), C12:0 (5.7 %), C14:0 (5.4 %), C12:0 3-OH (4.6 %), C18:0 (2.3 %) and summed feature 2 (comprising C14:0 3-OH and/or iso-C16:1I; 1.5 %).

The 16S rRNA gene of strain 5YN10-9T was amplified and sequenced as described by Kwon et al. (2003). This sequence was aligned and compared with those from the GenBank nucleotide database by using an online BLAST search. Phylogenetic trees were inferred by using the neighbour-joining method (Saitou & Nei, 1987). Evolutionary distance matrices for the neighbour-joining method were generated according to the Kimura two-parameter model (Kimura, 1980). Resultant tree topologies were evaluated by bootstrap analyses (Felsenstein, 1985) based on 1000 resamplings. According to 16S rRNA gene sequence analysis, strain 5YN10-9T was closely related to members of the family Rhodocyclaceae within the class Betaproteobacteria, in particular to members of the genera Azoarcus, Azovibrio, Thauera and Zoogloea (Fig. 2).

However, levels of 16S rRNA gene sequence similarity towards Azoarcus species (90.2–93.3 %), Azovibrio restrictus (92.7 %), Thauera species (90.9–93.3 %) and Zoogloea species (92.4–92.6 %) were low.

Strain 5YN10-9T could be phenotypically differentiated from members of the above genera based on yellow colony colour, inability to reduce nitrate, ability to hydrolyse urea, differential assimilation patterns and a relatively low DNA G+C content (Table 1). Based on comparisons of fatty acid contents, all strains included in the present study contained C16:0 and summed feature 3 as major components, which was consistent with data from previous studies.

*Summed feature 3 comprises C₁₆:₁ω7c and/or iso-C₁₅:₀ 2-OH; summed feature 5 comprises C₁₈:₁ω6,9c and/or anteiso-C₁₈:₀.

Fig. 2. Neighbour-joining phylogenetic tree derived from analysis of the 16S rRNA gene sequences of strain 5YN10-9ᵀ and other members of the family Rhodocyclaceae, class Betaproteobacteria. Numbers at nodes indicate levels of bootstrap support based on 1000 resamplings; only values above 40% are indicated. Bar, 0.01 substitutions per nucleotide position.
studies (Song et al., 2001; Xie & Yokota, 2006). However, strain 5YN10-9\textsuperscript{T} was unique in that it lacked C\textsubscript{10:0} 3-OH and had a low proportion of summed feature 3. C\textsubscript{12:0} 3-OH was found only in strain 5YN10-9\textsuperscript{T} and members of the genera Thauera and Zoogloea, and C\textsubscript{17:0} cyclo was present only in strain 5YN10-9\textsuperscript{T}, Azoarcus indigens LMG 9092\textsuperscript{T} and Thauera aromatica DSM 6984\textsuperscript{T} (Table 2). These phenotypic differences were further supported by their phylogenetic position based on 16S rRNA gene sequence data (Fig. 2); the distinct monophyletic line of strain 5YN10-9\textsuperscript{T} and its low 16S rRNA gene sequence similarity values with its closest related genera support the inclusion of this isolate in a new genus.

Based on combined phylogenetic and phenotypic data, strain 5YN10-9\textsuperscript{T} is considered to represent a novel species in a new genus, for which the name *Uliginosibacterium gangwonense* gen. nov., sp. nov. is proposed.

**Description of *Uliginosibacterium* gen. nov.**

*Uliginosibacterium* (Ul.i.gi.no.si.bac.te.ru.m. L. adj. uligosus wet, moist, marshy; L. neut. n. uligonosus a rod; N.L. neut. n. *Uliginosibacterium* a rod isolated from peat).

Gram-negative, strictly aerobic rods. Motile by means of a single polar flagellum. The major isoprenoid quinone is Q-8. The major fatty acids are C\textsubscript{16:0} and summed feature 3; C\textsubscript{18:1\textsubscript{ω7c}}, C\textsubscript{17:0} cyclo, C\textsubscript{12:0\textsubscript{ω}}, C\textsubscript{12:0} and C\textsubscript{12:0} 3-OH are present as minor components. On the basis of the results of 16S rRNA gene sequence comparisons, the genus belongs to the family *Rhodocyclaceae*, class *Betaproteobacteria*. The type species is *Uliginosibacterium gangwonense*.

**Description of *Uliginosibacterium gangwonense* sp. nov.**

*Uliginosibacterium gangwonense* (gang.won.en. N.L. neut. adj. gangwonense named after Gangwon Province in Korea, the geographical origin of the type strain of the species).

Has the following characteristics in addition to those given for the genus above. Colonies are irregular and yellow-coloured on R2A agar plates. Cells are 0.6–1.0 μm wide and 3.0–7.0 μm long. Temperature range for growth is 4–35 °C (optimum, 25–30 °C) and pH range for growth is 4.0–8.0 (optimum, pH 6.0–7.0). Unable to grow in the presence of 2 % NaCl. Catalase- and oxidase-positive. Accumulates poly-β-hydroxybutyrate. CM-cellulose, starch and Tween 80 are degraded, but casein, chitin, DNA, pectin and tyrosine are not. Positive for urease, aesculin hydrolysis, gelatin hydrolysis and β-galactosidase, but negative for nitrate reduction, indole production, glucose fermentation, and arginine dihydrolase (API 20NE). Positive for esterase (C4), leucine arylamidase, acid phosphatase, naphthol-AS-BI-phosphohydrolase, β-galactosidase, α-glucosidase and β-glucosidase, but negative for alkaline phosphatase, esterase lipase (C8), lipase (C14), valine arylamidase, cystine arylamidase, trypsin, z-chymotrypsin, x-galactosidase, β-glucuronidase, N-acetyl-β-glucosaminidase, β-mannosidase and x-fucosidase (API ZYM). Assimilates 3-glucose, L-arabinose, D-mannose, N-acetylgalactosamine, maltose, sucrose, glycerogen and L-serine, but not D-mannitol, potassium gluconate, capric acid, adipic acid, malic acid, trisodium citrate, phenylacetic acid, L- rvaline, D-ribose, inositol, itaconic acid, suberic acid, sodium malonate, sodium acetate, lactic acid, L-alanine, potassium 5-ketogluconate, 3-hydroxybenzoic acid, salcín, D-melibiose, L-fucose, D-sorbitol, propionic acid, valeric acid, Lhistidine, potassium 2-ketogluconate, 3-hydroxybutyric acid, 4-hydroxybenzoic acid or L-proline (API 20NE and API ID 32 GN). The DNA G+C content is 59.3 mol%.

The type strain, 5YN10-9\textsuperscript{T} (=KACC 11603\textsuperscript{T}=DSM 18521\textsuperscript{T}), was isolated from a wetland in Yongneup, Republic of Korea.
