Two Gram-negative, anaerobic, non-spore-forming, rod-shaped organisms were isolated from human amniotic fluid. Based on morphological and biochemical criteria, the strains were tentatively identified as Bacteroidaceae but they did not appear to correspond to any recognized species of this family. Comparative 16S rRNA gene sequencing studies showed the strains were highly related to each other and confirmed their placement in the genus Prevotella, but sequence divergence values of >4% with reference Prevotella species demonstrated that the organisms from human clinical sources represent a novel species. Phylogenetic analysis revealed the novel organism to be most closely related to Prevotella bivia, an organism frequently associated with pelvic inflammatory diseases. The major long-chain cellular fatty acids of the novel species consist of iso-C14:0, anteiso-C15:0, iso-C15:0, C16:0, iso-C16:0 and iso-3-OH-C17:0. Based on biochemical criteria and phylogenetic considerations, it is proposed that the unknown isolates from human amniotic fluid be assigned to a new species of the genus Prevotella, as Prevotella amnii sp. nov. The type strain of Prevotella amnii is CCUG 53648T (=JCM 14753T).

The genus Prevotella includes moderately saccharolytic, bile-sensitive species formally belonging to the genus Bacteroides (Shah & Collins, 1990). Many species of Prevotella have been isolated from human sources often associated with the oral cavity; indeed of the recently described species all have been isolated from this location (Downes et al., 2005; Sakamoto et al., 2004, 2005a, b). However, a number of species have been isolated from both healthy and infected tissues of the pelvic region, including the genitourinary tract, vagina and cervix (Brook & Frazier, 1997; Fredricks et al., 2005; Hyman et al., 2005; Mikamo et al., 1999; Puapermpoonsiri et al., 1997). During a continuing study of Gram-negative anaerobic rods, two strains were deposited with the Culture Collection of the University of Göteborg (CCUG), Sweden. Based on the results of a polyphasic taxonomic study, it is proposed that the isolates be assigned to the genus Prevotella, as Prevotella amnii sp. nov.

Isolate CCUG 53648T was recovered from the amniotic fluid of a 29-year-old female in 1999, the fluid was described as turbid and ill smelling; CCUG 43050 was isolated from a 26-year-old female in 2006, again from amniotic fluid. The unidentified organisms were cultured on Columbia agar supplemented with 5% defibrinated horse blood (Oxoid) at 37 °C, in an atmosphere of 85% nitrogen, 10% carbon dioxide and 5% hydrogen. The strains were characterized biochemically by using a combination of conventional tests as described in the VPI Anaerobe Laboratory Manual (Holdeman et al., 1977), and API rapid ID32AN and API ZYM systems according to the manufacturer’s instructions. Fermentation tests were performed using pre-reduced, anaerobically sterilized (PRAS) peptone-yeast (PY)-sugar broth tubes. All biochemical tests were performed in duplicate. Long-chain cellular fatty acids were extracted and analysed by GC (MIDI Sherlock) as described by Pot et al. (1994). End products of glucose metabolism were determined by GLC. 16S rRNA gene fragments were generated by PCR using universal primers and the amplified products were purified by using a QIAquick PCR purification kit and sequenced directly using primers to conserved regions of the 16S rRNA gene. Sequencing was performed using a PRISM Tag Dye-deoxy Terminator Cycle Sequencing Kit (Applied Biosystems) and an automatic DNA sequencer (model 373A; Applied Biosystems). The closest known relatives of the new isolates were determined by performing database searches using the FASTA3 search program (www.ebi.ac.uk/ fasta33/nucleotide.html; Pearson & Lipman, 1988). These sequences and those of other known related strains were retrieved from GenBank and aligned with the newly determined sequences using the program SEQTOLS (www.seqtols.dk). The resulting multiple sequence alignment was corrected manually using the program GENEREC (Nicholas et al., 1997) and a phylogenetic tree was constructed according to the neighbour-joining method.

The GenBank/EMBL/DDBJ accession number for the 16S rRNA gene sequence of strain CCUG 53648T is AM422125.
(Saitou & Nei, 1987) with the programs SEQTOOLS and TREEVIEW (Page, 1996). The stability of the groupings was estimated by bootstrap analysis (1000 replications) using the same programs.

The two isolates originating from human amniotic fluid were anaerobic, non-spore-forming, non-motile, Gram-negative rods. Typical cells were 0.8–3.0 × 0.5–1.5 μm. Colonies on blood agar plates after 48 h of incubation at 37 °C under anaerobic conditions were white, smooth, glistening with an entire edge and less than 1 mm in diameter. Cells were still viable after 6 h when left in air, and the catalase reaction was negative for the same period. No growth was observed in CO₂. Using the API Rapid ID32AN test system the unknown clinical isolates were positive for N-acetyl-β-D-glucosaminidase, alkaline phosphatase, alanine arylamidase, β-galactosidase, phospho-6-β-galactosidase, α-glucosidase, glutamyl-glutamic acid arylamidase and leucyl-glycine arylamidase. All other reactions in the API Rapid ID32AN test system were negative. Employing the API ZYM test kit, positive reactions were obtained for N-acetyl-β-D-glucosaminidase, N-AS-BI-phosphohydrolase, alkaline phosphatase, acid phosphatase, α-glucosidase and β-glucosidase. All other tests were negative using the API ZYM gallery. Indole was not produced and nitrate was not reduced. The major end products of glucose metabolism were acetic and succinic acids, with minor amounts of isovaleric, isocaproic and lactic acids also detected. The quantitative fatty acid profile of CCUG 53648T consisted of C₁₃:1 (0.4 %), C₁₄:0 (0.9 %), iso-C₁₄:0 (5.6 %), C₁₅:0 (0.3 %), iso-C₁₅:0 (16.4 %), anteiso-C₁₅:0 (32.3 %), iso-3-OH-C₁₅:0 (0.9 %), C₁₆:0 (6.4 %), iso-C₁₆:0 (9.7 %), 3OH-C₁₆:0 (2.0 %), iso-C₁₇:0 (3.4 %), anteiso-C₁₇:0 (2.9 %), iso-3-OH-C₁₇:0 (10.3 %), 2-OH-C₁₇:0 (1.1 %), C₁₈:0 (1.8 %) and C₁₈:1ω9c (2.9 %).

To determine the phylogenetic affinities between the isolates and to other species, the 16S rRNA gene sequences were amplified by PCR and sequenced. The two isolates CCUG 53648T and CCUG 43050 were found to be genetically highly related to each other, displaying 99.5 % 16S rRNA gene sequence similarity. Treeing analysis revealed the isolates were members of the Bacteroides-Prevotella-Porphyromonas rRNA supercluster of organisms (data not shown), demonstrating a specific affinity with members of the genus Prevotella. The phylogenetic position of CCUG 53648T using a reduced dataset is shown in Fig. 1. Treeing analysis clearly showed that this unknown bacterium represents a new subline within the genus Prevotella, sharing a branching node with Prevotella bivia (95.3 % 16S rRNA gene sequence similarity) supported by a 100 % bootstrap value. These two species were peripheral to a subcluster of organisms that included Prevotella distens, Prevotella intermedia, Prevotella nigrescens and Prevotella bivia sp. nov. CCUG 53648T (AM422129) and Prevotella melaninogenica ATCC 25845T (L16459).
Prevotella pallens, exhibiting lower levels of sequence similarity. There is no precise correlation between percentage 16S rRNA sequence divergence and species delineation, but it is generally recognized that divergence values of 3% or more are significant (Stackebrandt & Goebel, 1994). Support for the distinctiveness of the unknown bacterium isolated from amniotic fluid was also very evident from phenotypic analyses. Tests which are useful in distinguishing Prevotella amnii from some other related Prevotella species are shown in Table 1. Our analysis demonstrated that the closest phylogenetic relative was Prevotella bivia, an organism originally isolated from the endometrium and frequently recovered from patients with inflammatory diseases (Brook & Frazier, 1997; Puapermpoonsiri et al., 1997), including its recovery from amniotic fluid with preterm premature rupture of the associated membranes (Mikamo et al., 1999). In addition, sequence database searches revealed that a number of studies using culture-independent 16S rRNA gene sequencing strategies investigating the vaginal microflora of healthy women isolated a number of clonal sequences with almost 100% similarity to our two isolates. It is therefore likely that the organism reported here is present in healthy women, but in certain circumstances can be enriched for and involved in certain disease processes and should be regarded as an emerging opportunistic pathogen. Furthermore, it is likely that some isolates formally associated with pelvic diseases and presumptively identified as Prevotella bivia were in fact strains of the novel organism reported in this article. In particular, the unknown bacterium can be readily distinguished from Prevotella bivia by the production of phospho-6-β-galactosidase and its inability to produce α-fucosidase and glutamyl-glutamic acid arylamidase. We therefore consider the formal description of this novel species and the biochemical criteria will aid its identification and will facilitate its recognition in the routine laboratory to distinguish it from Prevotella bivia and thereby permit the recovery of additional strains. Furthermore, for unequivocal identification, 16S rRNA gene sequence analysis is recommended and is now being increasingly incorporated into the clinical laboratory setting. Based on the presented phenotypic and phylogenetic evidence, we consider the two unidentified isolates recovered from human amniotic fluid to be assigned to the genus Prevotella, as Prevotella amnii sp. nov.

**Description of Prevotella amnii sp. nov.**

*Prevotella amnii* (am’ni.i. Gr. n. amnion, inner membrane surrounding the fetus; N.L. gen. n. amnii, of the amnion, pertaining to the amniotic fluid from which the organism was first isolated).

Cells consist of Gram-negative rods that are anaerobic, non-motile and non-spore-forming. Typical cells are 0.8–3.0 × 0.5–1.5 μm. Colonies on blood agar plates after 48 h of incubation at 37°C under anaerobic conditions are white, smooth, glistening with an entire edge and less than 1 mm in diameter. Cells are still viable after 6 h when left in air. Using the API Rapid ID32AN test system, positive reactions are produced with N-acetyl-β-D-glucosaminidase, alkaline phosphatase, alanine arylamidase, phospho-6-β-galactosidase, β-galactosidase, α-glucosidase, glutamyl-glutamic acid arylamidase and leucyl glycine arylamidase. Using the API ZYM test kit, positive reactions are obtained for N-acetyl-β-D-glucosaminidase, N-AS-BI-phosphohydrolase, alkaline phosphatase, acid phosphatase, α-glucosidase and β-glucosidase. Indole is not produced and nitrate is not reduced. Aesculin is hydrolysed but gelatin is not. Glucose, lactose and maltose are fermented, but cellobiose, fructose, inositol, mannitol, melibiose, rhamnose, salicin, sucrose and trehalose are not. The major end products of glucose metabolism are acetic and succinic acids. The major long-chain cellular fatty acids consist of iso-C₁₄:₀, iso-C₁₅:₀, anteiso-C₁₅:₀, C₁₆:₀, iso-C₁₆:₀ and iso-3OH-C₁₇:₀.

The type strain, CCUG 53648T (=JCM 14753T), was isolated from human amniotic fluid.

**Acknowledgements**

We thank J. Euzéby for the naming of the novel species, Sofia Wernersson for DNA sequencing, and Elisabeth Ingaräs and Maria Ohlen for excellent technical assistance. We also thank the depositors of the strain to the CCUG, Inger Mattsny-Baltzer (Department of Clinical Bacteriology, University of Göteborg) and S. Kawash (PHLS, Eastern Hospital, Göteborg).
