A novel Gram-stain-negative, facultatively anaerobic, rod-shaped, agar-digesting bacterial strain, designated HQM9ᵀ, was isolated from the surface of the marine red alga Gelidium amansii collected from the intertidal zone of Weihai, China. Cells of HQM9ᵀ were 3.0–4.0 μm long and 0.2–0.3 μm wide and lacked flagella. The new isolate grew optimally at 28–30 °C, at pH 7.0–7.5, and in the presence of 2.5–3.0 % NaCl. The predominant cellular fatty acids were iso-C₁₅∶₀ and iso-C₁₇∶₀ 3-ÖH. The sole menaquinone was MK-6. The DNA G+C content was 33 mol%. The major polar lipids were comprised of phosphatidylethanolamine and four unknown polar lipids. Based on the 16S rRNA gene sequence, the closest relative was Aquimarina agaritica ZC₁ᵀ with 97.16 % sequence similarity, with which strain HQM9ᵀ formed a distinct cluster belonging to the genus Aquimarina in a phylogenetic tree. Moreover, average nucleotide identity and estimated DNA–DNA hybridization values between strains HQM9ᵀ and ZC₁ᵀ were 78.7 % and 12.50 ± 2.95 %, respectively. On the basis of phenotypic, chemotaxonomic and phylogenetic analysis, strain HQM9ᵀ represents the type strain of a novel species within the genus Aquimarina in the family Flavobacteriaceae, phylum Bacteroidetes, for which the name Aquimarina agarivorans sp. nov. is proposed. The type strain is HQM9ᵀ (=ATCC BAA-2612ᵀ=CICC 10835ᵀ).

The genus Aquimarina was first proposed by Nedashkovskaya et al. (2005) to accommodate heterotrophic, Gram-stain-negative, aerobic, dark-yellow or brownish-coloured, gliding bacteria that produce flexirubin-type pigments. To date, the genus comprises 16 established species, all of which were isolated from marine habitats, such as Aquimarina gracilis (Park et al., 2013) and Aquimarina amphiliecti (Kennedy et al., 2014) from marine animals, and Aquimarina longa (Yu et al., 2013), Aquimarina megaterium (Yu et al., 2014) and Aquimarina pacifica (Zhang et al., 2014) from seawater. Some species in the genus can degrade high-molecular-mass polysaccharides, which indicates that they play an important role in the recycling of carbon in marine environments. For example, Aquimarina agaritica (Lin et al., 2012), Aquimarina latercula (Oh et al., 2010) and 'Aquimarina litoralis' (Miyazaki et al., 2010) can produce agarase. In this study, we report on the taxonomic characterization of another Aquimarina-like and agar-digesting bacterium from a marine environment whose draft genome, sequenced previously, provides some basis for the phylogenetic analysis (Du et al., 2011).

In the course of screening agar-digesting bacteria, a Gram-stain-negative, facultatively anaerobic, rod-shaped and agar-digesting strain, designated HQM9ᵀ, was isolated from a red alga (Gelidium amansii) collected from the intertidal zone of Weihai, China (122° 3’ 42.8” E 37° 31’ 59.2” N). The red algal cells were crushed in a mortar and diluted with sterile saline. The dilution was then inoculated on marine agar 2216 (MA; Hope Bio-Technology). After incubation at 28 °C for 3–5 days, strain HQM9ᵀ, which formed yellow colonies with obvious hollows on the plate, was purified by successive subculture on MA. The purified strain was routinely preserved in marine broth 2216 (MB) containing 20 % glycerol (v/v) at −80 °C. The reference strain, Aquimarina agaritica ZC₁ᵀ, was kindly provided by Professor Zhong Hu, Shantou University, Guangdong, China.

Strain HQM9ᵀ was cultivated in MB at 28 °C for 2 days. Genomic DNA extraction, PCR amplification, sequencing and similarity calculations for 16S rRNA gene sequence were carried out as described previously (Liu et al., 2014). A phylogenetic dendrogram of strain HQM9ᵀ and
some closely related species, based on 16S rRNA gene sequence homology, was reconstructed by the neighbour-joining method with Kimura two-state parameter model analyses in the program MEGA version 6.0 (Tamura et al., 2013). The robustness of the tree topology was evaluated by bootstrap analyses based on 1000 resamplings.

On the basis of 16S rRNA gene sequence analysis, strain HQM9T showed highest similarity to *A. agarilytica* ZC1T (97.16 %), followed by *A. agarilytica* JAMB N27T (95.15 %), *Aquimarina addita* JC2680T (95.50 %), *A. latercula* LMG 1343T (95.43 %), *Aquimarinina intermedia* KMM 6258T (95.22 %), *Aquimarina macrocephali* JAMB N27T (95.15 %), 'A. litoralis' CNURIC011 (95.07 %) and *A. amphilecti* 92VT (95.03 %). Levels of 16S rRNA gene sequence similarity with other taxa were below 95.0 %. Strain HQM9T, *A. agarilytica* ZC1T and *A. addita* JC2680T formed a distinct lineage in the genus *Aquimarina* (Fig. 1), which suggested that the new isolate belongs to the genus *Aquimarina*.

Average nucleotide identity (ANI) was calculated online using the ExGenome Web service (http://www.ezbiocloud.net/ezgenome/ani; Kim et al., 2012). DNA–DNA hybridization (DDH) values were analysed using the genome-to-genome distance calculator (GGDC2.0) (Auch et al., 2010; Lai et al., 2014). The ANI and DDH values between strain HQM9T and *A. agarilytica* ZC1T were 78.7 % and 12.50 ± 2.95 %, respectively. Both values were below cut-off values for species differentiation (Richter & Rossello-Móra, 2009; Wayne et al., 1987; Bai et al., 2014). These results indicate that strain HQM9T represents a novel species in the genus *Aquimarina*.

Media for morphological and biochemical characterization were based on MA. Phenotypic features of the isolate and reference strain (i.e. colony morphology, pigment production and agar hydrolysis) were determined by cultivating the isolate on MA at 28 °C. The type of flagellum was observed under an electron microscope (Jem-1200; JEOL). Temperature range and optimum for cellular growth were...
measured at 4–45 °C (4, 10, 15, 20, 25, 28, 30, 33, 35, 40 and 45 °C) for up to 7 days. The pH range for growth tested was pH 5.5–9.0 at 0.5 pH unit intervals, by adding MES (pH 5.5 and 6.0), PIPES (pH 6.5 and 7.0), HEPES (pH 7.5 and 8.0), Tricine (pH 8.5) or CAPSO (pH 9.0 and 9.5) to MB at concentrations of 20 mM. The effect of NaCl on growth was determined as described previously (Du et al., 2014). Flexirubin-type pigment was detected by the KOH test (Bernardet et al., 2002). Gliding motility was observed by oil-immersion phase-contrast microscopy (AX70; Olympus) according to the method described by Bowman (2000). Growth under anaerobic conditions was determined after incubation on MA in an anaerobic chamber for 2 weeks at 28 °C. Antibiotic sensitivity was investigated on MA plates by using discs (Tianhe) containing different antibiotics for 2 days at 28 °C.

Physiological and biochemical characteristics were determined with API 20E and API ZYM kits (bioMérieux) according to the manufacturer’s instructions, except that the suspension medium was replaced by 3.0 % (w/v) NaCl solution. Acid production from carbohydrates was assessed by using the API 50CH fermentation kit (bioMérieux) according to the manufacturer’s instructions. The salinity of the 50CH medium was adjusted by addition of autoclaved 30.0 % (w/v) NaCl solution before inoculation. The API 50CH strips were read after 3 days of incubation at 28 °C. Carbon source utilization was tested using Biolog GEN III 50CH strips were read after 3 days of incubation at 28–30.0 % (w/v) NaCl solution before inoculation. The API 50CH medium was adjusted by addition of autoclaved according to the manufacturer’s instructions. The salinity of NaCl solution. Acid production from carbohydrates was assessed by using the API 50CH fermentation kit (bioMérieux) according to the manufacturer’s instructions, except that *Data from Lin et al. (2012).

*Data from Lin et al. (2012).
and by the absence of aminolipid. The DNA G+C content of the novel strain was 33 mol%, a value in the range of those for recognized species of the genus *Aquimarina* (Table 1).

Despite the common chemotaxonomic features, there were some different phenotypic characteristics between strain HQM9\(^T\) and closely related known species of the genus *Aquimarina* (Table 1). Strain HQM9\(^T\) differed from its closest phylogenetic neighbour, *A. agarilytica* ZCI\(^T\), in that it was able to grow at 33 °C and in the presence of 5.0 % (w/v) NaCl; it was negative for hydrolysis of starch and resistance to streptomycin; and HQM9\(^T\) produced acid from sucrose but not D-galactose. Strain HQM9\(^T\) was also distinguishable from its second closest phylogenetic neighbour, *A. addita* JC2680\(^T\), by its ability to hydrolyse agar but not starch or Tween 80. In view of the low values of sequence similarity, ANI and DDH, and the phenotypic, chemotaxonomic and phylogenetic analyses, strain HQM9\(^T\) represents a novel species within the genus *Aquimarina*, for which the name *Aquimarina agarivorans* sp. nov. is proposed.

**Description of *Aquimarina agarivorans* sp. nov.**

Cells are Gram-stain-negative, non-motile, facultatively anaerobic, 3.0–4.0 μm long and 0.2–0.3 μm wide, and lack flagella. Colonies are yellow, circular with entire edges, convex and butyrous with a diameter of 1.0–1.5 mm after growing on MA for 2 days. Growth occurs at 10–33 °C (optimum, 28–30 °C) and at pH 6.0–8.5 (optimum, pH 7.0–7.5). Cells require sea salts for growth (range, 1.0–5.0%; optimum, 2.5–3.0%). Flexirubin-type pigment is not formed (KOH-test-negative). Positive for catalase and oxidase, negative for H₂S production, indole production and nitrate reduction. Agar is degraded; casein, chitin, gelatin, starch, cellulose, urea and Tween 80 are not degraded. Acids are produced from glycerol, D-xylene, D-glucose, maltose, D-fructose, inositol, D-mannitol, D-sorbitol, methyl α-D glucopyranoside, aesculin, sucrose, trehalose, phosphatidylethanolamine, glycolipid and eight unknown lipids.

The type strain, HQM9\(^T\) (=ATCC BAA-2612\(^T\)=CICC 10835\(^T\)), was isolated from the surface of the marine red alga *Gelidium amansii*, collected from the intertidal zone of Weihai (Shandong Province, China).
