CHARACTERISTICS OF MOTILE CURVED RODS IN VAGINAL SECRETIONS

Regional Public Health Laboratory and * Department of Sexually Transmitted Diseases, General Hospital, Newcastle upon Tyne NE4 6BE

SUMMARY. Motile curved rods seen in vaginal secretions have been isolated on Columbia agar supplemented with 5% human blood and vitamin K. Growth occurred anaerobically and in 5% oxygen but not in more aerobic conditions. There were two distinct groups of these organisms, distinguishable by morphology, biochemical activity and susceptibility to metronidazole. All isolates were sensitive to a wide range of antimicrobial agents, with the exception of nalidixic acid and polymyxin, but one group was resistant to metronidazole. There was little difference between the results of tests of susceptibility to aminoglycosides or to metronidazole performed in anaerobic and microaerophilic conditions. Motile curved rods were isolated from 18 of 80 patients with a clinical diagnosis of non-specific vaginitis, but from only two of 39 without the disease.

INTRODUCTION

Curved rods with a characteristic motility have been reported in vaginal secretions of patients with a clinical diagnosis of non-specific vaginitis (NSV) (Hjelm et al., 1981; Skarin et al., 1981; Phillips and Taylor, 1982; Sprott et al., 1982). In this paper we report on the morphology, cultural and biochemical characteristics, and the susceptibility to antimicrobial agents, of such organisms isolated in this laboratory.

MATERIALS AND METHODS

Patients. One hundred and nineteen patients attending the Department of Sexually Transmitted Diseases, Newcastle General Hospital, were included in the study.

Specimens. Gram-stained smears from urethral and endocervical swabs were examined by microscopy for gram-negative diplococci and the swabs were plated on Modified New York City Medium (Young, 1978) for the isolation of Neisseria gonorrhoeae. A second endocervical swab was placed in transport medium for inoculation on to McCoy cells for the isolation of Chlamydia trachomatis. The discharge from the posterior vaginal pool was suspended in normal saline and smears were examined by dark ground microscopy for yeasts, Trichomonas vaginalis and motile curved rods. Gram-stained smears for microscopy were prepared by a technique in which decolorisation was performed by applying acetone for 2–3 s. Swabs from the posterior vaginal pool were cultured for Gardnerella vaginalis and curved rods.

Received 28 Jul. 1982; revised version accepted 29 Oct. 1982
Culture media and growth conditions. The medium for primary isolation and all subsequent studies of the growth of motile curved rods and *G. vaginalis* was Columbia Agar Base (Lab M) supplemented with human blood 5% and vitamin K 1 mg/L (CBA). After inoculation, plates were incubated at 37°C for at least 48 h in 90% H₂ and 10% CO₂ in an anaerobic jar fitted with a cold palladium catalyst (Don Whitley Scientific Ltd, Green Lane, Baildon, Shipley, West Yorks). All curved rods were subsequently subcultured (i) aerobically, (ii) in 5% CO₂ in a candle jar, and (iii) in 10% CO₂ in a Gas Kit CO₂ system (Oxoid), at 37°C for 4 days.

Fluid media used were Todd-Hewitt Broth (Oxoid) and Robertson’s Cooked Meat Medium (Difco) with and without haemin (5 mg/L), sodium formate (2 g/L), sodium fumarate (3 g/L) and vitamin K (1 mg/L). These were incubated anaerobically and growth was determined by viable counts on CBA performed by the method of Miles, Misra and Irwin (1938).

The ability of the isolates to grow in microaerophilic conditions was examined by incubation in anaerobic jar without a catalyst. In a series of experiments, partial removal of air by evacuation was monitored with an Edwards pressure gauge and the pressure in the jar was restored to atmospheric pressure by admission of 10% CO₂ in H₂, leaving final concentrations of oxygen from 0.3 to 7%.

Gram-variable coccobacilli that showed enhancement of growth by 10% CO₂ or in anaerobic conditions, ß-haemolysis on CBA, and a zone of inhibition around a disk containing 100 µg of metronidazole, were identified as *G. vaginalis* (Taylor et al., 1982).

Characterisation of motile curved rods. Motility was examined by dark-ground microscopy of the water of condensation from 24-h CBA-slope cultures of each strain. Because in preliminary studies these organisms failed to grow consistently in liquid media, the inoculum for all biochemical tests was taken directly from CBA plates incubated at 37°C for 48 h. Hippurate hydrolysis (Skirrow and Benjamin, 1982) and arginine hydrolysis (Thornley, 1960) were examined after incubating the inoculated media aerobically at 37°C for 2 and 24 h respectively. The aesculin hydrolysis test (Rotimi, Faulkner and Duerden, 1980) was incubated both aerobically and anaerobically and examined after 24 h, and the ONPG test (Lowe, 1962) was incubated aerobically for 24 h. Indole production was tested by both Kovacs’ and Ehrlich’s reagents (Cowan, 1974) using 48-h cultures in cooked meat medium. For each of the following tests, the first of the methods described by Cowan (1974) was used: nitrate reduction (incubated anaerobically for 3 or 7 days), oxidase, and urease. Catalase production was tested by transferring organisms from a colony to a drop of hydrogen peroxide on a glass slide.

Electron microscopy. Organisms grown on CBA were fixed and embedded by the methods of Narang (1982). Thin sections (50 nm) were stained with uranyl acetate and lead citrate and examined at 60 kV in an AEI electron microscope. In addition, grids for electron microscopy were prepared with organisms in the water of condensation from 24-h CBA-slope cultures. The cells were washed by resuspending the centrifuged deposit in phosphate buffered saline followed by centrifugation at 1200g for 15 min, this procedure being repeated three times. Grids were prepared by low speed centrifugation as described by Narang and Codd (1979), except that the washed bacterial suspension was examined both undiluted and at a dilution of 1 in 10. The prepared grids were negatively stained with phosphotungstic acid (pH 6-6) and examined by electron microscopy.

Antimicrobial sensitivity tests. The antimicrobial agents tested were penicillin, tetracycline, lincomycin, erythromycin, chloramphenicol, polymyxin, nalidixic acid, streptomycin, gentamicin, metronidazole and the hydroxy-metabolite of metronidazole—1-(hydroxyethyl)-2-hydroxyethyl-6-nitroimidazole. Minimum inhibitory concentrations (MIC) of the above agents were determined by incorporating twofold dilutions in CBA. Growth from agar plates incubated for 48 h was suspended in saline to give c. 10⁶ cfu/ml and inoculated on to the plates with a Denley Multipoint inoculator delivering 0.01 ml. Plates were read after incubation anaerobically for 48 h at 37°C; the end point was the lowest concentration that totally inhibited growth. In addition the MIC of metronidazole, gentamicin and streptomycin was determined in microaerophilic conditions. Control organisms were *Staphylococcus aureus* strain NCTC 6571, *Pseudomonas aeruginosa* strain NCTC 10662, *Bacteroides fragilis* strain NCTC 8560 and strains of *Escherichia coli* and *B. asaccharolyticus* isolated and characterised in this laboratory by the methods of Cowan (1974) and Duerden et al. (1976).
MOTILE CURVED RODS IN VAGINAL SECRETIONS

RESULTS

Of the 119 patients examined, 33 did not have a vaginal discharge. _N. gonorrhoeae_, _Chlamydia trachomatis_, _Candida_ species or _G. vaginalis_ were isolated from two thirds of these patients, but motile curved rods were found in only two (table I). Specimens from most of the other 86 patients (with vaginal discharge) yielded one or more of these named organisms or _T. vaginalis_, and motile curved rods were isolated from 18.

Gram-stained smears from some patients with increased vaginal secretions showed few pus cells and a mixture of organisms, including curved rods that stained poorly when counterstained with neutral red but better when dilute carbol fuchsin was used. These curved organisms grew on CBA, appearing as minute transparent or grey colonies after incubation anaerobically for 48 h. Although vitamin K was included in the medium, subsequent studies have indicated that it was not a required growth factor. Morphologically, two types were distinguishable. Eight strains were short curved rods (SCR) 1–2 μm in length; all cells retained some violet dye, and this was more marked after repeated subculture. The remaining 12 strains were long curved rods (LCR) 2–4 μm in length, which appeared red, though often with a central violet area. The LCR strains produced α-haemolysis after prolonged culture on CBA and developed a dark brown pigment after incubation for 10–14 days. Both groups of organisms were very motile with a rapid darting movement; larger forms of the LCR strains also showed serpentine movements. Attempts to grow isolates in liquid media were disappointing. In Robertson's cooked meat medium and Todd-Hewitt broth, with an initial inoculum of $10^4$–$10^6$ organisms, the viable count after incubation for 48 h was in the range $3 \times 10^6$–$3 \times 10^7$ cfu/ml. The addition of sodium formate, sodium fumarate, haemin and vitamin K did not improve growth.

Electron microscopy revealed curved rods of varied size. The SCR had a diameter of c. 0·3 μm, rounded ends, and 2–6 subpolar flagella with a common point of origin on the concave side (fig. 1). The LCR had flagella arising from several different points (fig. 2).

All strains of the curved rods gave negative results in tests for catalase, oxidase, urease and indole production. Other biochemical characteristics are shown in table II;

* 5% and 10% (candle jar and Gas Kit system).

...jar or Gas Kit system), but all strains grew anaerobically and in concentrations of oxygen up to 5%. For comparison, B. fragilis grew in concentrations of oxygen up to only 1%, and B. asaccharolyticus up to only 0.4%. In contrast, Pseudomonas aeruginosa failed to grow anaerobically but grew in a concentration of oxygen as low as 0.3%.

All strains were very sensitive to the antimicrobials tested, with the exceptions of nalidixic acid, polymyxin and metronidazole (table IV). There was a notable difference between the two groups in their sensitivity to metronidazole, the range of MIC being 0.5–4 mg/L for the LCR, but 16–1000 mg/L for the SCR. The levels of MIC of metronidazole, however, were similar when each strain was tested in anaerobic conditions and in the presence of 1% oxygen. When the organisms were re-tested with gentamicin and streptomycin in increased oxygen concentrations, the MIC remained the same or showed at most a two-fold reduction. In contrast the MIC of these
aminoglycosides for *S. aureus* strain NCTC 6571 and *E. coli* was 16–32 times higher in anaerobic conditions than when tested in microaerophilic conditions.

**DISCUSSION**

Motile curved bacilli were first isolated from the vagina by Curtis (1913) who described them as strictly anaerobic and gram-negative with up to six flagella. Moore (1954) in a subsequent study of curved rods from the vagina described them as “more or less gram negative” with a single flagellum; he also reported a similar organism with up to six flagella, which produced haemolysis on blood agar. Recently other workers have reported motile curved rods in vaginal discharge from women with NSV: Hjelm *et al.* (1981) found them in 30% of such patients, Skarin *et al.* (1981) in 8.6% and Phillips and Taylor (1982) in 11%. In the present study, 18 (22.5%) of 80 patients with NSV harboured the organism compared with two (5.1%) of 39 without the disease. Our findings indicate that these curved rods constitute two distinct groups distinguishable by their colonial appearance, microscopic morphology, biochemical reactions and sensitivity to metronidazole. It is clear that the prevalence rates already reported provide only limited information in view of the ill-defined taxonomic status of these organisms.

Their cultural requirements are unusual: they grow well anaerobically but, unlike obligate anaerobes, they also grow in 5% oxygen although not in higher concentrations. Despite their ability to grow in the presence of oxygen the LCR are very sensitive to metronidazole (MIC 0.5–4 mg/L) and even the SCR (MIC 16–1000 mg/L) are more sensitive than facultative anaerobes (Fuzi and Csukas, 1970; Prince *et al.*, 1969). In this respect these organisms resemble *G. vaginalis*, but unlike the latter they are only marginally more sensitive to the hydroxy-metabolite of metronidazole (Ralph and Amatnieks, 1980). Further evidence of the unusual metabolism of these organisms is their sensitivity to the aminoglycosides in both anaerobic and microaerophilic conditions. Normally, obligate anaerobes are highly resistant to these agents and, as our findings confirm, facultative anaerobes are much less sensitive in anaerobic
MOTILE CURVED RODS IN VAGINAL SECRETIONS

conditions than in the presence of oxygen (Bondi, Dietz and Spaulding, 1946; Verklin and Mandell, 1977).

It appears, therefore, that these organisms represent a new group of bacteria, probably first reported by Curtis (1913). They appear to be distinct from the anaerobic bacteria isolated by Fontaine et al. (1982) from men with urethritis. Unlike our isolates, these were oxidase positive and motile with polar flagella; it was suggested that they were related to Vibrio succinogenes. Less certain is the relationship between our strains and those described by Skarin et al. (1981) and Spiegel et al. (1981) which had characteristics consistent with Wolinella succinogenes. Although some strains of Wolinella grow well in the presence of 5% oxygen they have polar flagella and their sensitivity to antimicrobials differs markedly from that of our isolates (Tanner et al., 1981).

Clearly the variety of these organisms is such that further taxonomic studies are required before their possible aetiological role in NSV can be established. Such studies are being carried out in this laboratory.

We wish to thank May and Baker Ltd, Dagenham, Essex, for donating the hydroxy metabolite of metronidazole, 1-(2-hydroxyethyl)-2-hydroxymethyl-6-nitroimidazole. We also thank Mrs A. Chappell and Mrs C. Laidlow for typing the manuscript.
