A novel real-time PCR (RT-PCR) assay was developed for detection of *Bordetella pertussis* in respiratory specimens by targeting the pertactin gene. *In vitro* evaluation with reference strains and quality control samples showed analytical sensitivity equivalent to and specificity superior to those of PCR assays which target the IS481 element. The pertactin-based RT-PCR assay offers better discrimination between *B. pertussis* and other *Bordetella* species than previously described assays.

INTRODUCTION

*Bordetella pertussis* is the aetiological agent of whooping cough or pertussis. In the non-vaccinated population, it primarily affects children less than 6 months of age. The most common manifestations of *B. pertussis* infection are whooping cough and bronchitis with complications including pneumonia, seizures, encephalopathy and possibly sudden infant death (Mattoo & Cherry, 2005). During the last 15 years, the incidence of pertussis has increased again in different regions of the world despite intensive programmes of infant vaccination (Cordova et al., 2000; De Melker et al., 2000; De Schutter et al., 2003; Gonzalez Moran et al., 2002; Khetsuriani et al., 2001). Adults and adolescents act as a reservoir for infection in very young infants who are not yet fully immunized and who experience severe morbidity. This reservoir exists because vaccination in childhood induces protection for a limited time only (Mattoo & Cherry, 2005; Von Konig et al., 2002). The emergence and dissemination of *B. pertussis* variant strains that are antigenically different from vaccine strains is another possible cause of this phenomenon (Weber et al., 2001).

In this context, rapid and accurate diagnostic tests for pertussis appear to be needed for improved management of cases and protection of infants. Most of the PCR-based methods described so far for the detection of *B. pertussis* target the multi-copy insertion sequence IS481 (Chan et al., 2002; Cloud et al., 2003; Poddar, 2003; Reischl et al., 2001), which is also found in other *Bordetella* species (Muyldermans et al., 2005). Here, we describe a novel PCR assay for specific detection of *B. pertussis* that we have designed by targeting the single-copy pertactin gene, a 69 kDa outer-membrane protein which is an important virulence factor of *B. pertussis*. The real-time pertactin PCR (pertactin RT-PCR) can be combined with sequence analysis of 16S rRNA genes for the identification of other species of *Bordetella*.

METHODS

Bacterial isolates. The assay specificity was evaluated on strains of *Bordetella* (n=8) and non-*Bordetella* species (n=20), including: *Bordetella pertussis* (ATCC 9340 and 9797), *Bordetella parapertussis*, *Bordetella bronchiseptica*, *Bordetella holmesii*, *Bordetella hinzii*, *Bordetella trematum*, *Bordetella avium*, *Staphylococcus aureus*, *Staphylococcus epidermidis*, *Staphylococcus hominis*, *Streptococcus pneumoniae*, *Stenotrophomonas maltophilia*, *Pseudomonas aeruginosa*, *Klebsiella pneumoniae*, *Acinetobacter baumannii*, *Morganella morganii*, *Enterobacter aerogenes*, *Citrobacter freundii*, *Proteus vulgaris*, *Burkholderia cepacia* (genomovar 1), *Escherichia coli*, *Moraxella catarrhalis*, *Serratia marcescens*, *Mycobacterium tuberculosis*, *Legionella pneumophila* and *Mycoplasma pneumoniae* (type 1 and 2).

All *Bordetella* strains were cultured on Regan–Lowe charcoal agar containing 10% defibrinated horse blood and cephalixin (40 mg l⁻¹) (Oxoid). Nucleic acids were extracted from one colony of fresh culture using the QiaAmp DNA mini kit (Qiagen), according to the manufacturer’s instructions.

RT-PCR. The primers and probe for the real-time method (Fig. 1) were chosen by alignment of all described pertactin genes and determination of the consensus sequence using the Primer Express software (Applied Biosystems). The fragment to be amplified was checked by BLAST (http://www.ncbi.nlm.nih.gov/BLAST) to avoid false-positive signals due to sequence homology. The TaqMan assays were performed on a GeneAmp 5700 (Applied Biosystems) in a 25 µl reaction mix containing 12.5 µl TaqMan Universal Master Mix, which included optimized concentrations of AmpliTaq Gold DNA polymerase, AmpErase UNG, dNTPs with UTP, MgCl₂ and buffer (Applied Biosystems), 0.375 µl of each primer (300 nM) and 0.83 µl of the TaqMan probe (66 nM), purchased from MWG-Biotech AG.
DNA quantification. Concentrations of *B. pertussis* extracted DNA were measured using the NanoDrop ND-1000 spectrophotometer. Tenfold serial dilutions were prepared in water using extracted DNA from three *B. pertussis* strains (ATCC 9340 and 9797 and Bord201). DNA dilutions ranging from 6 log₁₀ to 0.1 log₁₀ copy ml⁻¹ were used to determine the detection threshold of the assay.

DNA sequence analysis. To confirm the identification of *Bordetella* species, 16S rRNA gene PCR was performed using primers 16S rDNA sequences were submitted to BLAST software for identification. The 16S rRNA gene PCR was performed using primers 16S rDNA forward 5'-TACGTTGTTCCGG-AATTCAAGGCGTGAGCGCC-TAMRA-3' (Taqman probe). Alignment positions were followed using the complete sequence of the allele 1 pertactin gene. The accession numbers used were: AJ011091 (pm1); AJ011092 (pm2); AJ011093 (pm3); AJ011015 (pm4); AJ011016 (pm5); AJ132095 (pm6); AJ133784 (pm7); AJ133245 (pm8); AJ315611 (pm9); AJ784875 (pm10); AJ507842 (pm11).

**RESULTS AND DISCUSSION**

The pertactin RT-PCR was evaluated with the strains listed in Methods and showed 100% analytical specificity for *B. pertussis*. Two *B. pertussis* positive control strains and 10 *B. pertussis* pertactin variants typed with PFGE in a previous study (De Schutter et al., 2003) were correctly identified by RT-PCR. All *Bordetella* species were correctly identified with the 16S rRNA gene sequence analysis with high degrees of similarity (over 98%).

Standard curves were established with three strains of *B. pertussis*. The linearity of the assay was observed over a range of 6 log₁₀ of magnitude. The pertactin RT-PCR assay showed a limit of detection of 1 log₁₀ copies of *B. pertussis* DNA ml⁻¹. Inter-assay variability was tested by running the same controls with 10 replicates on different days; intra-assay variability was assessed using the three standard curves in five replicates for the same experiment. Using three *B. pertussis* strains, ATCC 9797, ATCC 9340 and Bord201, the detection rate of the assay was 90%, 100% and 100% at 10 log₁₀ copies ml⁻¹ of each strain. At 1 log₁₀ copies ml⁻¹, the detection rate fell to 50% for strain ATCC 9797, 80% for strain ATCC 9340 but still achieved 90% for strain Bord201.

We participated in two European external quality assessment ring trials for *B. pertussis* molecular detection (Muyldermans et al., 2005). The first trial checked the sensitivity of protocols and the second one, containing *Bordetella non-pertussis*, tested the specificity. The analytical sensitivity of the pertactin RT-PCR varied from 9 to 30 c.f.u. ml⁻¹ whereas other laboratories using other PCR methods/target gene reported results ranging from 3 to 9000 c.f.u. ml⁻¹. The pertactin RT-PCR assay showed 100% specificity while other participants’ results varied in specificity from 73 to 87%, mainly due to misidentification of *B. holmesii* and *B. bronchiseptica* (Muyldermans et al., 2005).

RT-PCR is increasingly used in laboratory diagnostics. As compared with bacteriological culture, this technique is simple, fast and very sensitive (Dragsted et al., 2004). However, the high sensitivity can lead to false-positive results, depending on the design of the assay. For *B. pertussis*,
the main target gene used is the insertion sequence IS481 (Chan et al., 2002; Cloud et al., 2003; Poddar, 2003; Reischl et al., 2001), which is present in 50–100 copies. Insertion sequences are attractive because they occur in multiple copies, which increases the sensitivity of the PCR. However, IS481 is also present in \textit{B. holmesii} and in \textit{B. bronchiseptica} (Muyldermans et al., 2005). In recent years, several reports showed pertussis-like infections that were attributed to \textit{B. holmesii}; however, its clinical significance is not yet fully understood (Greig et al., 2001; Mazenga et al., 2000; Reischl et al., 2001; Russell et al., 2001). Insertion sequences of eubacteria are transposable elements that can provide sequence homologies at various sites on DNA molecules and they can result in DNA rearrangements and even in horizontal transfer (Arber, 2000; Mahillon & Chandler, 1998). Thus protocols using insertion sequences should be controlled by another region of the genome or another method, following previous recommendations (Fry et al., 2004). The novel pertactin PCR assay described here showed an excellent analytical sensitivity for \textit{B. pertussis} DNA detection compared to assays targeting insertion sequences. Furthermore, this novel assay alleviated the problems of cross-reactivity seen for other PCR strategies with other \textit{Bordetella} species. Therefore, there was no requirement for a confirmation test. Although the pertactin gene exists in 11 known variants (Muyldermans et al., 2004), the region targeted by the pertactin RT-PCR assay described here is conserved in all of them (Fig. 1). In summary, in the clinical laboratory, this novel RT-PCR assay appears promising for rapid diagnosis of pertussis. Awaiting further clinical validation, we recommend the use of the pertactin RT-PCR assay as a confirmatory test for specimens showing a positive result with an IS481-based assay.

ACKNOWLEDGEMENTS

We thank Gaetan Muyldermans, Department of Microbiology of the Academisch Ziekenhuis, Vrije Universiteit Brussels (VUB), Belgium, for providing \textit{Bordetella} strains. We also thank Nathalie De Fierlant for the technical assistance with the NanoDrop system.
