Curcumin alone and in combination with augmentin protects against pulmonary inflammation and acute lung injury generated during \textit{Klebsiella pneumoniae} B5055-induced lung infection in BALB/c mice

Shruti Bansal and Sanjay Chhibber

Department of Microbiology, Panjab University, Chandigarh 160014, India

Acute lung injuries due to acute lung infections remain a major cause of mortality. Thus a combination of an antibiotic and a compound with immunomodulatory and anti-inflammatory activities can help to overcome acute lung infection-induced injuries. Curcumin derived from the rhizome of turmeric has been used for decades and it exhibits anti-inflammatory, anti-carcinogenic, immunomodulatory properties by downregulation of various inflammatory mediators. Keeping these properties in mind, we investigated the anti-inflammatory properties of curcumin in a mouse model of acute inflammation by introducing \textit{Klebsiella pneumoniae} B5055 into BALB/c mice via the intranasal route. Intranasal instillation of bacteria in this mouse model of acute pneumonia-induced inflammation resulted in a significant increase in neutrophil infiltration in the lungs along with increased production of various inflammatory mediators [i.e. malondialdehyde (MDA), myeloperoxidase (MPO), nitric oxide (NO), tumour necrosis factor (TNF-\(\alpha\))] in the lung tissue. The animals that received curcumin alone orally or in combination with augmentin, 15 days prior to bacterial instillation into the lungs via the intranasal route, showed a significant (\(P<0.05\)) decrease in neutrophil influx into the lungs and a significant (\(P<0.05\)) decrease in the production of MDA, NO, MPO activity and TNF-\(\alpha\) levels. Augmentin treatment alone did not decrease the MDA, MPO, NO and TNF-\(\alpha\) levels significantly (\(P>0.05\)) as compared to the control group. We therefore conclude that curcumin ameliorates lung inflammation induced by \textit{K. pneumoniae} B5055 without significantly (\(P<0.05\)) decreasing the bacterial load in the lung tissue whereas augmentin takes care of bacterial proliferation. Hence, curcumin can be used as an adjunct therapy along with antibiotics as an anti-inflammatory or an immunomodulatory agent in the case of acute lung infection.

INTRODUCTION

\textit{Klebsiella pneumoniae} is an opportunistic pathogen that causes community-acquired and nosocomial infections, mainly in immunocompromised individuals. Infections caused by it range from mild urinary infections to severe bacteraemia and pneumonia with a high rate of mortality and morbidity (Cortes \textit{et al.}, 2002; Struve & Krogfelt, 2004). Various antibiotics have been used to treat infections caused by \textit{K. pneumoniae} but emergence of strains resistant to commercially available antibiotics has made the treatment of infections quite difficult (Saint & Chenoweth, 2003). The combination of amoxicillin and clavulanic acid, i.e. augmentin, has been the first choice of treatment for community-acquired as well as nosocomial lower respiratory tract infections (Legnani, 1997). This is because of the presence of the clavulanate component, which protects the amoxicillin component from degradation by \(\beta\)-lactamases produced by this organism, thereby retaining its original potency and antibacterial activity against \textit{Klebsiella} (Hunter \textit{et al.}, 1980).

Most antibiotics reduce bacterial load and do not provide protection against organ damage generated because of an exaggerated immune response (Woo \textit{et al.}, 2002). In order to control the over-stimulated stage of inflammation, various strategies have been used in the past, such as the use of various corticosteroids for the treatment of \textit{Mycobacterium tuberculosis} infection, use of anti-tumour necrosis factor (TNF) antibodies or TNF blockers, cyclooxygenase (COX-2) inhibitors, and leukotriene synthetase and 3-hydroxy-3-methylglutaryl coenzyme A reductase inhibitors (Tasaka \textit{et al.}, 2002). However, most of these agents failed during clinical trials and did not provide protection to patients suffering from acute infections (Tasaka \textit{et al.}, 2002). Therefore, there is a need for newer immunomodulatory agents to be developed which target only the overwhelming activity of the immune system while keeping its protective function intact. The combination of an anti-inflammatory agent with an antibiotic can serve as a good option in

Abbreviations: MDA, malondialdehyde; MPO, myeloperoxidase; NO, nitric oxide; TNF, tumour necrosis factor.
containing both the infectious agent as well as the harmful action of the over-stimulated immune response. One such herbal compound is turmeric-derived curcumin, which is known to possess anti-inflammatory properties and has been used for decades to curb inflammation (Huang et al., 1994, 1997; Kawamori et al., 1999; Sharma et al., 2005).

Curcumin is a naturally occurring yellow pigment found in the spice turmeric derived from the rhizome of the plant *Curcuma longa*. It has been used for centuries in the Indian subcontinent as a dietary spice and for the treatment of a variety of illnesses, such as the common cold, coughs, jaundice, inflammatory bowel conditions, arthritis, etc. (Ammon & Wahl, 1991). Extensive research has shown that curcumin mediates its anti-inflammatory effects through the downregulation of inflammatory transcription factors (such as nuclear factor κB), enzymes (such as COX-2 and 5-lipooxygenase) and cytokines (such as TNF, interleukin-1 and interleukin-6) (Aggarwal & Sung, 2008). Curcumin has been characterized as safe by health authorities such as the Food and Drug Administration in the USA, and the Food and Agriculture Organization/World Health Organization. Curcumin has entered the phase I and II clinical trial level in the last 10–15 years (Strimpos & Sharma, 2008) and phase I studies show that people can tolerate curcumin at a dose as high as 8 g per day (Cheng et al., 2001).

Working in this direction, we tried to evaluate the pulmonary inflammatory damage in compartmentalized inflammation in a mouse model of pneumonia and evaluated the protective potential of a herbal compound, curcumin, alone and along with augmentin.

**METHODS**

**Bacterial strain.** *Klebsiella pneumoniae* B5055 (O1:K2), initially obtained from Dr Mathia Trautmann, Department of Medical Microbiology and Hygiene, University of Ulm, Germany, and maintained in the laboratory, was used in the study. This strain was selected because it expresses O1 and K2 serotypes, which are the most commonly encountered O and K types found in a clinical situation.

**Animals.** A total of 80 pathogen-free BALB/c mice of either sex, 6–8 weeks old, weighing 20–25 g were procured from the central animal house of Panjab University, Chandigarh, India. Animals were kept in weeks old, weighing 20–25 g were procured from the central animal house of Panjab University, Chandigarh, India. Animals were kept in a separate tube and its concentration was quantified by measuring the MPO activity using a spectrophotometric method as proposed by Greenberger et al. (1995). Briefly, the lungs were removed, weighed to determine the wet weight and then homogenized in 2 ml normal saline. Serial dilutions of the homogenized lung tissue were made, plated on nutrient agar plates, incubated at 37 °C for 24 h and quantitative bacterial counts were determined.

**Induction of acute lung infection.** Acute lung infection in mice was induced with *K. pneumoniae* B5055, following the original method of Held et al. (1998) modified by Yadav et al. (2003). A single isolated colony of *K. pneumoniae* B5055 obtained on a nutrient agar plate was transferred to 50 ml nutrient broth and incubated at 37 °C for 18 h. Cells were harvested by centrifugation at 5000 r.p.m. for 15 min. The bacterial pellet so obtained was given three washings with sterile PBS (0.1 M, pH 7.2). The final pellet was suspended in a minimum volume of PBS (0.1 M, pH 7.2) to get the desired concentration (OD_{600}=0.03, 10^5 c.f.u. ml^{-1}).

Mice were then given 10^7 c.f.u. ml^{-1} of *K. pneumoniae* B5055 intranasally in a volume of 50 μl while holding the mouse in an upright position without any anaesthesia. After infection, animals were sacrificed on different days post-infection by cervical dislocation and lungs were removed aseptically and examined for bacterial load and various other inflammatory parameters.

**Quantification of bacteria in lungs.** Mice were sacrificed on different days post-infection by cervical dislocation, lungs were removed aseptically and then homogenized in 1 ml normal saline. Serial dilutions of the homogenized lung tissue were made, plated on nutrient agar plates, incubated at 37 °C for 24 h and quantitative bacterial counts were determined.

The lung homogenate from each mouse was also processed for the following parameters.

**Malondialdehyde (MDA) estimation.** The extent of tissue damage in terms of lipid peroxidation was estimated by measuring the amount of MDA by the method of Ohkawa et al. (1979). In brief, 0.2 ml of the lung homogenate was mixed with 4 ml 0.045 M sulphuric acid, 1.5 ml of freshly prepared 0.8 % thiobarbituric acid and 0.2 ml 8.1 % SDS. This mixture was then kept in a boiling water bath for 1 h. After cooling the mixture under tap water, 5.0 ml butanol : pyridine (15:1) was added and the mixture was shaken vigorously. The contents were centrifuged at 4000 r.p.m. for 10 min, the upper organic layer was taken in a separate tube and its A_{532} was taken. The MDA concentration was expressed as μmol (mg protein)^{-1}.

**Myeloperoxidase (MPO) estimation.** Pulmonary neutrophil infiltration was quantified by measuring the MPO activity using a spectrophotometric method as proposed by Greenberger et al. (1995). Briefly, the lungs were removed, weighed to determine the wet weight and then homogenized in 2 ml homogenizing solution containing 50 mM potassium phosphate buffer (pH 6.0) with 0.5 % hexadecyltrimethyl-ammonium bromide and 5 mM EDTA. The homogenate was sonicated and centrifuged at 15000 g for 15 min. The supernatant was mixed in a ratio of 1:15 with assay buffer comprising 100 mM potassium phosphate buffer (pH 6.0), 0.167 mg o-dianisidine hydrochloride ml^{-1} and 0.0005 % hydrogen peroxide. MPO activity was assayed by measuring the change in A_{460} from 0 min to 4 min over intervals of 30 s.

**Nitric oxide (NO) estimation.** The nitric level was estimated in the lung homogenate according to the method of Tsai et al. (1997). Lung homogenate (0.1 ml) was mixed with 0.4 ml PBS (0.1 M, pH 7.2) and 2 ml Griess reagent. Then 2 ml trichloroacetic acid was added and the mixture was vortexed and incubated for 20 min. The mixture was then centrifuged at 14000 g for 10 min and the A_{540} of the supernatant was taken. The nitric concentration was determined from a standard curve prepared with 0.1 ml 100 μM sodium nitrite.

**Estimation of TNF-α levels.** Assay for TNF-α in the lung homogenates was performed by ELISA using a commercially available cytokine kit from BD Biosciences, i.e. BD OptEIA Mouse TNF-α ELISA. In brief, lungs were homogenized in 1 ml lysis buffer containing 0.5 % Triton X-
100, 150 mM NaCl, 15 mM Tris, 1 mM CaCl$_2$ and 1 mM MgCl$_2$ (pH 7.4). Homogenates were then incubated on ice for 30 min and centrifuged at 2500 r.p.m. for 10 min. Supernatants were then collected in sterile Eppendorf tubes, passed through a 0.45 μm pore-size filter and stored at −70 °C for the assessment of TNF-α levels. The BD OptEIA test is a solid-phase sandwich ELISA. The wells were read at 450 nm, the concentration of TNF-α in the test sample was determined from a standard curve prepared from the standard given along with the kit, and the results were expressed as pg ml$^{-1}$ of TNF-α released.

Histopathological examination. Lungs were removed aseptically, immersed in 10% formalin fixative and processed for histological examination. The lung tissue was embedded in paraffin wax and cut into 4–6 μm thick sections using a microtome. After this, the sections were stained with haematoxylin and eosin for assessment of the degree of neutrophil infiltration.

Statistical analysis. Results were analysed statistically by applying Student’s t-test for comparing various parameters in treated and untreated control mice. Differences were considered statistically significant if P-values were less than 0.05.

RESULTS

Effect of treatment with curcumin and augmentin individually or in combination on the bacterial count in the lungs of mice infected via the intranasal route with K. pneumoniae B5055

As shown in Fig. 1, an increase in the bacterial count was noticed in the lungs of control mice infected with K. pneumoniae from day 1. It reached its peak on day 3, after which the bacterial counts started declining. In the curcumin-treated group, no decrease in bacterial counts was observed and the counts were quite similar to those seen in the control group. In contrast, bacterial counts in the lungs of mice which received augmentin alone or in combination with curcumin showed a significant (P <0.05) decline. In this group also curcumin did not offer any extra protection in terms of bacterial numbers as the counts were similar in both groups.

Effect of treatment with curcumin and augmentin individually or in combination on MPO levels in the lung homogenates of mice infected via the intranasal route with K. pneumoniae B5055

K. pneumoniae B5055-induced pulmonary infection in mice caused a profound increase in MPO activity (Fig. 2), indicating increased influx and activity of neutrophils at the site of infection in the lungs of the control group. Curcumin pre-treatment alone or in combination with augmentin significantly reduced (P <0.05) the MPO activity in the lungs of infected mice by 2.5-fold as compared to the control. In the group treated with augmentin alone, the MPO activity increased until the 3rd day and then declined. A comparison of MPO levels showed that they increased in all the groups until the 3rd post-infection day but the fall in MPO levels in curcumin-treated animals was much higher than in the other groups on the 5th post-infection day (P <0.05) onwards.

Effect of treatment with curcumin and augmentin individually or in combination on the NO levels in the lung homogenates of mice infected via the intranasal route with K. pneumoniae B5055

The results in Fig. 3 show that the lung homogenates of mice infected intranasally with K. pneumoniae B5055 contained detectable amounts of NO. There was an
increase in NO production in the control animals and maximum levels were observed on the 3rd day post-infection. Levels of NO in curcumin-treated groups were lower and there was no significant difference in levels of NO in the curcumin- and curcumin+augmentin-treated groups. Treatment with augmentin alone did not cause a decrease in the NO concentration and the levels were similar to those seen in the control group.

Effect of treatment with curcumin and augmentin individually or in combination on the MDA levels in the lung homogenates of mice infected via the intranasal route with \textit{K. pneumoniae} B5055

Fig. 4 depicts the level of MDA in the lungs of mice infected with \textit{K. pneumoniae} B5055. MDA levels increased significantly in the lungs of animals infected with \textit{K. pneumoniae} B5055.
pneumoniae B5055, reached a peak on the 3rd day and thereafter started declining. MDA levels in the augmentin-treated group were quite similar to the levels in the control group. Animals which were treated with curcumin alone or in combination with augmentin showed a fourfold decrease, thereby indicating reduced injury to lung tissue. A comparison of MDA levels on different days showed curcumin to be effective from day 1 following infection.

**Effect of treatment with curcumin and augmentin individually or in combination on the TNF-α levels in the lungs of mice infected via the intranasal route with K. pneumoniae B5055**

Pro-inflammatory cytokines such as TNF-α play an important role during the pathogenesis of K. pneumoniae B5055-induced pneumonia. As shown in Fig. 5, the levels of TNF-α increased significantly following bacterial infection and maximum levels were observed in the control groups on the 3rd post-infection day. Treatment with curcumin alone as well as in combination with augmentin downregulated TNF-α production in comparison to the control group. However, augmentin treatment alone did not show any negative effect on TNF-α production as the levels observed were quite similar to those seen in the control group on all days following infection.

**Effect of treatment with curcumin and augmentin individually or in combination on the neutrophil infiltration into the lungs of mice infected via the intranasal route with K. pneumoniae B5055**

Curcumin treatment alone or in combination with augmentin significantly decreased the neutrophil infiltration in the lungs of mice infected with K. pneumoniae B5055 (Fig. 6c, d) as compared to the control group (Fig. 6a). However, augmentin treatment alone did not show any effect on neutrophil infiltration in the lungs of infected animals (Fig. 6b).

**DISCUSSION**

An attempt was made in this study to explore the anti-inflammatory effect of curcumin alone as well as in combination with augmentin in an acute lung injury model. On the basis of the results of all the different parameters employed in this study, induction of acute lung inflammation following instillation of K. pneumoniae was observed. Pre-treatment of animals with curcumin 15 days prior to infection with K. pneumoniae did not give rise to any antibacterial activity. In contrast, bacterial counts in animals treated with augmentin alone or in combination with curcumin declined following treatment, indicating that curcumin did not interfere with the antibacterial effect of augmentin. The results are in agreement with an earlier finding from our laboratory where it was shown that immunomodulatory agents do not interfere with antibiotic action (Kumar & Chhibber, 2008) and hence can be used in conjunction.

Acute inflammation in the lungs is characterized by increased activity of neutrophils (Kooguchi et al., 1998; Maus et al., 2003). The migration of neutrophils at the site of acute inflammation involves the activity of various inflammatory cytokines and chemokines, and expression of various cell surface leukocyte and endothelial adhesion molecules (Rousseau et al., 2000; Robson et al., 2001; Maus et al., 2002). There are reports showing that infection of airway epithelial cells by pathogens such as Streptococcus pneumoniae, Mycoplasma pneumoniae and group B...
streptococci triggers the secretion of interleukin-8 and increases the surface levels of intercellular cell adhesion molecule-1 (ICAM-1) (Doran et al., 2002; Murdoch et al., 2002; Yang et al., 2002; Mikamo et al., 2004). It is likely that infection with *K. pneumoniae* B5055 also resulted in an increase in ICAM-1 levels, which might have contributed towards the influx of neutrophils in the lung alveoli as confirmed by histopathological examination of tissue. There have been reports in the past that curcumin downregulates neutrophil infiltration in the tissue spaces by decreasing the expression of adhesion molecules such as ICAM-1 and vascular cell adhesion molecule-1 on endothelial cells (Ohene-Abuakwa & Pignatelli, 2000). Similar results were observed in this study on histopathological examination of lung tissue of mice fed on curcumin. The animals which were treated with curcumin alone or in combination with augmentin showed no signs of inflammation and the lung alveoli were completely devoid of neutrophils. However, treatment with augmentin alone had no effect on neutrophil infiltration in the lung alveoli and the alveoli were completely filled with neutrophils similar to that seen in the lungs of the control group. Enzyme MPO is also an indirect indicator of neutrophil infiltration and its levels correlated with neutrophil numbers on all days of infection.

NO generated during acute infection causes tissue damage by acting as a free radical and by generating more active species such as peroxynitrite which lead to lipid peroxidation of the cell membrane of various host cells (Koo et al., 1995; Sittipunt et al., 2001) and result in acute lung injury (Wang et al., 2002; Baron et al., 2004). NO synthase inhibitors are known to decrease acute lung injury and microvascular leakage caused during endotoxaemia (Kristof et al., 1998). However, NO synthase inhibition with inhibitors such as NG-monomethyl-L-arginine in patients with acute lung injury worsened their cardiac function and increased the mortality rate (Nava et al., 1991; Cobb et al., 1992; Minnard et al., 1994). In contrast, curcumin alone or in combination with augmentin in the present study led to decreased NO free radical production in the lungs of mice infected with *K. pneumoniae* B5055 without any adverse effects. This can be explained on the basis of earlier findings as curcumin has been found to neutralize both reactive oxygen and reactive nitrogen species, which play an important role during inflammatory processes such as inflammatory bowel disease (Brouet & Ohshima, 1995; Bhauimk et al., 2000; Ukil et al., 2003). Since augmentin alone showed no effect on NO generation, it is concluded that in combination with curcumin both antibacterial and anti-inflammatory effects can be generated using both the agents.

The level of cellular injury which might have occurred due to release of reactive oxygen species as a result of lipid peroxidation was estimated in terms of MDA levels in lung homogenates of mice suffering from acute pneumonia. In an earlier study, Kaur et al. (2006) demonstrated that curcumin reduced the levels of MDA in a model of endotoxin-induced hepatic dysfunction. Treatment of mice with curcumin alone or in combination with augmentin in the present study also resulted in decreased MDA levels in infected lung tissue thereby reducing lung injury. These results further suggest that curcumin can be used as an adjunct therapy along with the antibiotic augmentin, resulting in clearance of bacteria from the lungs along with protection to tissue from injury due to an exaggerated immune response during pneumonia. Treatment with curcumin alone or in combination
with augmentin also resulted in decreased production of lung TNF-α. These results are in accordance with earlier observations where curcumin was shown to downregulate levels of TNF-α during inflammatory bowel disease and chronic lung disease (Literat et al., 2001; Ukil et al., 2003). These results are significant as TNF-α is known to play an important role in the pathogenesis of acute lung infection (Shalaby et al., 1985; Marcho et al., 1991; Tsan et al., 1995).

The results of the present study clearly demonstrate the positive effect of curcumin as reduced acute lung injury associated with pneumonia was observed in treated animals. The major protection was due to its immunomodulatory or anti-inflammatory action, which resulted in decreased production of various inflammatory markers such as TNF-α, NO, MPO and MDA and neutrophil recruitment. As the immune system plays an important role in the pathogenesis of pneumonia-associated lung injury and mortality, this strategy will prove meaningful in preventing increased inflammatory pulmonary damage associated with pneumonia following bacterial infection. Moreover, since curcumin has no side effects, is cost-effective and is a part of our daily diet, it can serve as a very good alternative or complementary form of medicine to curb inflammation.
