
The Folic Acid and Serine Nutrition of Leuconostoc mesenteroides P60 (Streptococcus equinus P60)

BY JUNE LASCELLES,* M. J. CROSS AND D. D. WOODS

Microbiology Unit, Department of Biochemistry,
University of Oxford

SUMMARY: Leuconostoc mesenteroides P60 (Streptococcus equinus P60) requires serine for growth under normal conditions. On a medium containing relatively high concentrations of glycine it can dispense with serine provided that (a) pyridoxal is present, and (b) either Leucovorin (folinic acid) is added or the atmosphere is enriched with CO₂. Increasing concentrations of CO₂ or Leucovorin decrease the concentration of glycine required to support growth without added serine. Pyridoxal is not necessary for optimal growth with added serine, but the required concentration of the latter is twice as great.

Higher concentrations of p-aminobenzoic acid or Leucovorin are required for growth on glycine than on serine. Leucovorin replaces p-aminobenzoic acid for growth on serine, and both this factor and CO₂ for growth on glycine. With the basal medium used (containing purines and all other amino-acids) thymidine supports growth in the absence of p-aminobenzoic acid only when serine is added.

Growth is not inhibited by sulphonamide when Leucovorin is present; with p-aminobenzoic acid there is the usual competition. Pteroylglutamic acid is inactive with this organism.

A valid assay for serine is possible, even with high concentrations of glycine present, when precautions are taken to destroy either Leucovorin or pyridoxal in the samples, and to prevent the atmosphere becoming enriched with CO₂.

In connexion with work on the synthesis of serine by cell suspensions of Streptococcus faecalis R (Lascelles & Woods, to be published) it was necessary to devise an assay for small quantities of serine in the presence of relatively high concentrations of glycine and of members of the folic acid group of growth factors. Attention was given to microbiological assay since chemical methods proved insufficiently sensitive or otherwise unsatisfactory with the type of material to be analysed. Amongst micro-organisms reported to require serine for growth, Leuconostoc mesenteroides P 60 has been frequently used or suggested for assay of serine (Dunn, 1949; Steele, Sauberlich, Reynolds & Baumann, 1949; Barton-Wright, 1952). The nutritional requirement of this organism for serine was therefore investigated in detail, particularly in relation to the effect of various folic acid derivatives and of varying amounts of glycine. Some of these results have already been briefly reported (Lascelles & Woods, 1950; Lascelles, Cross & Woods, 1951).

It was found that, under certain conditions of growth, Ln. mesenteroides P 60 could synthesize serine for itself. Nevertheless, it was possible to devise a valid assay by taking steps to ensure that such conditions did not exist. The growth experiments upon which these conclusions are based are reported in detail since they also yielded considerable information concerning the final stage of serine synthesis by this organism. The literature bearing on this matter will be considered in the Discussion in relation to the present results.

* Beit Memorial Fellow at the time of this work.
MATERIALS AND METHODS

The organism. *Leuconostoc mesenteroides* P 60 (American Type Culture Collection, no. 7881) was maintained in stab culture on medium B 1 of Nimmo-Smith, Lascelles & Woods (1948). Stock cultures were subcultivated fortnightly and incubated 24 hr. at 37°; they were stored at 2°. It has recently been reported (McCleskey, 1952) that strain P 60 of this organism is improperly placed in the genus *Leucoizostoc* and is closely related to *Streptococcus equinus*. The original name is retained here (even if incorrect) to avoid confusion in reference to earlier work.

Media. The chemically-defined basal medium (medium L) was a modification of that used by Sauberlich & Baumann (1948) for the assay of *Ln. citrovorum* factor with that organism. In particular, the concentration of DL-alanine was increased since this overcame the inhibition of growth which occurred in the absence of pyridoxal when the serine concentration exceeded 2 × 10⁻⁴M.

Medium L contained (per litre final volume): DL-alanine, 450 mg.; L-arginine hydrochloride, 200 mg.; DL-aspartic acid, 200 mg.; L-asparagine, 400 mg.; DL-cysteine hydrochloride, 130 mg.; DL-glutamic acid, 600 mg.; L-histidine hydrochloride, 60 mg.; DL-isoleucine, 240 mg.; DL-leucine, 240 mg.; DL-lysine hydrochloride, 400 mg.; DL-methionine, 100 mg.; DL-phenylalanine, 100 mg.; DL-proline, 200 mg.; DL-threonine, 200 mg.; DL-tryptophan, 40 mg.; DL-tyrosine, 200 mg.; DL-valine, 240 mg.; glucose, 20 g.; sodium acetate trihydrate, 20 g.; NH₄Cl, 8 g.; KH₂PO₄, 0·6 g.; Na₂HPO₄·12H₂O, 0·6 g.; MgSO₄·7H₂O, 0·4 g.; MnSO₄·4H₂O, 20 mg.; FeSO₄·7H₂O, 20 mg.; adenine, guanine, xanthine and uracil, each 10 mg.; riboflavin, 0·5 mg.; nicotinic acid, 1 mg.; calcium pantothenate, 0·6 mg.; thiamine hydrochloride, 0·6 mg.; biotin, 1 μg. Before the addition of the other constituents the amino-acids were dissolved in 40 ml. N-NaOH, the solution diluted to 200 ml. and brought to pH 6–7 with 10N-HCl. The complete medium (quantities for 1 l.) was adjusted to pH 6–8, boiled gently for 3 min., filtered and diluted to 500 ml. (double strength medium L).

In tests designed to show the effect of p-aminobenzoic acid and related substances it was necessary to treat the amino acids with charcoal. After dissolving in N-NaOH as above the solution was brought to pH 3 with 10N-HCl. The complete medium (quantities for 1 l.) was adjusted to pH 6–8, boiled gently for 3 min., filtered and diluted to 500 ml. (double strength medium L).

In tests designed to show the effect of p-aminobenzoic acid and related substances it was necessary to treat the amino acids with charcoal. After dissolving in N-NaOH as above the solution was brought to pH 3 with 10N-HCl. The complete medium (quantities for 1 l.) was adjusted to pH 6–8, boiled gently for 3 min., filtered and diluted to 500 ml. (double strength medium L).

Medium L₆ was used for the assay of serine. It was prepared from medium L by adding (final concn.) 5 × 10⁻⁴M-glycine; 10⁻⁶M-p-aminobenzoic acid, 10⁻⁷M-pteroylglutamic acid and, when desired, 2 × 10⁻⁷M-pyridoxal.

Procedure. The double strength medium (L or L₆) was distributed in 1 ml. quantities in hard glass tubes (5 × ½ in.). After adding test materials and water to a total volume of 1·9 ml., the tubes were autoclaved 7 min. at 10 lb./sq.in. Leucovorin (synthetic *Ln. citrovorum* factor) and pyridoxal were added when required as sterile solutions after the autoclaving.

The inoculum was derived from a fresh stab culture in medium B 1 which
was subcultured into tryptose-glucose broth (medium B2, Nimmo-Smith et al. 1948) and incubated 24 hr. at 37°. The cells were centrifuged out, suspended in the original culture volume of water and diluted 1/50; each tube of test medium was inoculated with 0.1 ml. (about 4 x 10^6 cells/ml. final medium). For experiments on the effect of p-aminobenzoic acid and derivatives it was necessary first to wash the cells three times with the culture volume of 0.85 % (w/v) NaCl.

Incubation was at 37° for 42-46 hr. For atmospheres other than air the adapted 'Kilner' fruit-preserving jars referred to by Nimmo-Smith et al. (1948) were used.

The extent of growth is recorded as the galvanometer reading given by an EEL photoelectric colorimeter (Evans Electroselenium Co.) using 0.25 in. tubes and a neutral density filter; the uninoculated medium was used to obtain the zero setting. A culture containing 0.29 mg. dry weight cells/ml. gave a reading of 10; there was a linear relationship between reading and dry weight of cells up to a reading of 35.

Special chemicals. ‘Leucovorin’ (Ca salt pentahydrate, 99 % purity) was a gift from Dr H. P. Broquist (Lederle Laboratories); a stock solution (10^-3 M) was prepared in sterile water; it was not further sterilized. ‘Aldehyde-free’ pteroylglutamic acid was kindly supplied by Dr T. H. Jukes of the same Laboratories; a 10^-3 M stock solution was prepared by dissolving the solid in 10^-2 M-NaHCO₃. Pyridoxal hydrochloride was a gift from Dr K. Folkers (Merck Inc.); the stock solution in water (2 x 10^-3 M) was sterilized by Seitz-filtration. All three solutions were stored at -20° in the dark. Thymidine was a gift from Dr E. E. Snell and L-serine from Dr A. Neuberger.

RESULTS

Effect of carbon dioxide on the ability of glycine to replace serine

When cultures were incubated in air, N₂ or H₂, serine was essential for growth even with high concentrations of glycine present. In atmospheres containing 5 % (v/v) CO₂, however, serine was not required provided there was a sufficiently high concentration of glycine (Table 1).

The concentration of glycine required to give a given growth response in the absence of serine was a function of the partial pressure of CO₂ (Fig. 1a); as the latter was increased the necessary amount of glycine decreased. Maximum growth in the presence of 5 % CO₂ was reached with 0.01 M-glycine.

With an optimal concentration of serine present added CO₂ was not needed (Table 1). When, however, the serine concentration was suboptimal, the presence of CO₂ increased growth markedly (Fig. 1b); under these conditions it is probable, therefore, that the available serine is supplemented by synthesis from glycine.

Replacement of CO₂ by dicarboxylic acids. Citrate, oxaloacetate and α-ketoglutarate, but only at concentrations of 0.01 M and above, partially replaced the need for added CO₂ for growth with glycine (Table 1, Exp. 2). Other
carboxylic acids, including formate, were without effect. Certain dicarboxylic acids have been shown to replace CO₂ for the growth of *Escherichia coli* (Lwoff & Monod, 1947; Ajl & Werkman, 1948).

**Table 1. Effect of carbon dioxide and certain carboxylic acids on growth in the presence of serine or glycine**

Medium L was supplemented with *p*-aminobenzoic acid (10⁻⁴M), pteroylglutamic acid (10⁻⁶M), pyridoxal (2 x 10⁻⁷M) and the other substances shown. The carboxylic acids were added as the sodium salts (pH 6-8); oxaloacetate and α-ketoglutarate were sterilized by filtration. When citrate was added the medium was further supplemented with (µg./ml.) MgSO₄·7H₂O, 400; MnSO₄·4H₂O, 80; FeSO₄·(NH₄)₂SO₄·6H₂O, 30. Incubation 48 hr. in the atmosphere shown.

* Glycine (5 x 10⁻⁴M) was also present (see text).
† No growth occurred when glycine was omitted.

Relative activity of serine and glycine. In the presence of added CO₂ the concentration of glycine required for optimal growth was about 50 times that of serine (cf. Fig. 1a, b). With serine present, and whether or not incubation was in an atmosphere enriched with CO₂, glycine was still essential, though the molar concentration was diminished to 0.02–0.05 of that required with serine absent (Fig. 2). This requirement for glycine when serine is present in excess shows that the organism cannot convert serine to glycine (if it does so at all) at a rate sufficient to support growth; it can, however, carry out the converse reaction when the atmosphere is enriched with CO₂. Certain animal tissues are able actively to convert serine to glycine (Shemin, 1946).

Requirement for pyridoxal. When serine was present in optimal concentration pyridoxal increased growth only slightly; it was essential for growth when glycine plus CO₂ replaced serine (Table 2, Exp. 1). This was still true at the limiting effective concentrations of both glycine and CO₂ (Table 2, Exp. 2). Pyridoxal is therefore required, directly or indirectly, for the conversion of glycine to serine.

When serine was present, but in suboptimal concentration, pyridoxal markedly increased growth: about twice as much serine was required for

Fig. 3. Response of *Ln. mesenteroides* P60 to L- and DL-serine in the presence and absence of pyridoxal (B6). Medium L was supplemented with 10^{-4}M-p-aminobenzoic acid, 10^{-7}M-pteroylglutamic acid and 5 × 10^{-4}M-glycine. Pyridoxal (2 × 10^{-7}M) present (---) or absent (--); L-serine (○), DL-serine (●). Incubation 44 hr. in air.

It appears that this organism cannot use the D-isomer. The increased stimulation of growth by pyridoxal at limiting serine concentrations again suggests that under these conditions the supply of serine is supplemented by synthesis from glycine.

Requirement for members of the folic acid group

Pennington (1946) first reported p-aminobenzoic acid to be essential for the growth of *Ln. mesenteroides* P60; other strains of this organism which do not respond to p-aminobenzoic acid have been found to need pteroylglutamic
Nutrition of Leuconostoc mesenteroides P60

acid (Whiteside-Carlson & Carlson, 1949). The requirement of the present strain for members of the folic acid group was tested on medium L, based on charcoal-treated amino acids (p. 268). Best growth on this medium was about 70% of that on the medium containing untreated amino acids.

*p-Aminobenzoic acid.* This substance was essential for growth either on a medium containing serine or on one in which serine was replaced (as above) by high concentrations of glycine and a CO₂-enriched atmosphere. Under the latter conditions, however, the quantitative requirement for p-aminobenzoic acid was increased to about 5 times that when serine was supplied (Fig. 4a). An atmosphere containing added CO₂ did not influence the concentration of

![Graph](image)

Fig. 4a and b. Response of *Ln. mesenteroides* P60 to p-aminobenzoic acid (a) and Leucovorin (b) for growth in serine or high concentrations of glycine. Medium L was supplemented with 2×10⁻⁷M-pyridoxal and 10⁻³M-DL-serine plus 5×10⁻⁴M-glycine (●—●) or 10⁻⁴M-glycine (○—○, +增量). Incubation 44 hr. in 5% CO₂ in N₂ (○—○, ●—●) or N₂ only (+增量).

*p-aminobenzoic acid* required for growth with serine present. The requirement for p-aminobenzoic acid was maintained over the whole range of effective concentrations of glycine and CO₂; thus in the limiting conditions of 2×10⁻²M-glycine with 0.065% CO₂ and 10⁻³M-glycine with 20% CO₂ (each giving only half-optimal growth) the need was still absolute. The increased need for p-aminobenzoic acid for growth in the absence of serine provides evidence that the factor (or some derivative) is concerned in the conversion of glycine to serine as well as in other reactions essential for growth.

*Other members of the group.* Neither pteroylglutamic acid nor its N¹⁰-formyl derivative supported growth at concentrations up to a thousand times that effective with p-aminobenzoic acid; this was true both for growth with serine and with glycine plus CO₂ (Table 3). Pteroic acid and rhizopterin
(N\textsuperscript{10}-formylpterolic acid) were also inactive. It is probable, therefore, either that these substances do not permeate the cell or that the organism cannot convert them (as it presumably does p-aminobenzoic acid) to the form in which folic acid ultimately has function in metabolism. Experiments with the N\textsuperscript{5}-formyltetrahydro derivative of pteroylglutamic acid (Leucovorin), which did replace p-aminobenzoic acid for growth, are discussed later.

Table 3. Replacement of p-aminobenzoic acid by members of the folic acid group and by thymidine

Medium L was based on charcoal-treated amino acids and was supplemented with 2\times10^{-7}\text{M}-pyridoxal and the substances shown. Incubation 44 hr. in 5 % (v/v) CO\textsubscript{2} in H\textsubscript{2}.

* Glycine (5 \times 10^{-4}M) was also added.

Replacement of p-aminobenzoic acid by thymidine. Thymine or thymidine has frequently been found to be a component of mixtures which will support the growth of organisms requiring members of the folic acid group in the absence of these factors. Shive, Eakin, Harding, Ravel & Sutherland (1948) found the inhibition of growth of a strain of \textit{Ln. mesenteroides} by a methylpteroylglutamic acid to be overcome by thymidine, but not thymine, as well as by pteroylglutamic acid.

With the present strain thymidine supported growth in the absence of p-aminobenzoic acid when the medium contained serine, but not when the latter was replaced by glycine plus CO\textsubscript{2} (Table 3); thymine was inactive, which suggests that the organism cannot convert it to the deoxyriboside. When the medium (which already contains purine and an amino acid mixture) is supplemented with serine and thymidine it apparently contains all metabolites in the synthesis of which p-aminobenzoic acid is concerned. When, however, the supply of serine is dependent on formation from glycine, p-aminobenzoic acid is still required; this confirms the specific function of the growth factor in the conversion of glycine to serine. With \textit{Strep. faecalis} and a similar type of medium, Broquist & Snell (see Snell, 1951) found the growth requirement for folic acid to be abolished when thymine and serine were added; without thymine, folic acid was again required and the need was increased tenfold when serine was also omitted.
There is now very strong evidence that the naturally occurring factor required for the growth of *Ln. citrovorum* (ATCC 8081)* is (-)L-5-formyl-5,6,7,8-tetrahydropyroteroylglutamic acid. The synthetic material (Leucovorin, folinic acid-SF) is a mixture of the (+)L- and (-)L-isomers of this compound and has half the activity of the crystalline natural factor (Roth, Hultquist, Fahrenbach, Cosulich, Broquist, Brockman, Smith, Parker, Stokstad & Jukes, 1952; Cosulich, Smith & Broquist, 1952; Sauberlich, 1952; Pohland, Flynn, Jones & Shive, 1951; Bond, Bardos, Sibley & Shive, 1949; Keresztesy & Silverman, 1951). Leucovorin also replaces pteroylglutamate for the growth of *Strep. faecalis* R and *Lactobacillus casei*, but its ability to promote growth of organisms responding to *p*-aminobenzoic acid has not been reported.

### Table 4. Growth with high concentration of glycine: replacement of CO₂ and *p*-aminobenzoic acid by Leucovorin

Medium L (based on charcoal-treated amino acids) was supplemented with 10⁻⁴M-glycine and the substances shown. Incubation: 44 hr. in atmosphere stated.

'Acid-treated' Leucovorin was prepared by bringing an aqueous solution to pH 2 with N-HCl, autoclaving at 10 lb. pressure/sq.in. for 7 min. and neutralizing (pH 7) with sterile N-NaOH; it was added to the sterile basal medium.

*Replacement of *p*-aminobenzoic acid and of CO₂. Leucovorin had a dual effect with *Ln. mesenteroides* P60. First, it replaced *p*-aminobenzoic acid both for growth with added serine and for growth with glycine plus CO₂ (serine absent). Secondly, it abolished the need for added CO₂ under the latter conditions; with optimal concentrations of Leucovorin (10⁻⁸M and above) growth with 0.01M-glycine in an atmosphere of N₂ was equal to that found with *p*-aminobenzoic acid or Leucovorin in an atmosphere enriched with CO₂ (Fig. 4b, Table 4).

* It has recently been reported (Felton & Niven, 1958) that this organism is incorrectly identified as *Ln. citrovorum*; it is a typical strain of *Pediococcus cerevisiae*. 

In a series of experiments Leucovorin was 2–5 times less active on a molar basis than p-aminobenzoic acid in supporting growth either with serine or high concentrations of glycine (cf. Fig. 4a with 4b); thus the concentrations required for half-maximal growth were (Leucovorin first): $5.4 \times 10^{-10}$ and $3.6 \times 10^{-10}$ with serine, and $6.4 \times 10^{-9}$ and $1.4 \times 10^{-9}$ with glycine. These figures are taken from the experiments of Fig. 4 with a gas phase containing CO$_2$ in each case. The presence of CO$_2$ had no significant effect on the quantitative requirement for either growth factor when serine was present, or on that for Leucovorin for growth on glycine (Fig. 4b); it was as usual required for growth on glycine with p-aminobenzoic acid.

A difference of a factor of two between the intrinsic activities of Leucovorin and p-aminobenzoic acid is possible since the former contains only 50% of the natural isomeride.

The growth factor activity of Leucovorin for *Ln. citrovorum* is lost by autoclaving it at pH 2. After such treatment (Table 4, Exp. 2) it no longer replaced CO$_2$ for growth on the glycine medium (serine absent), but it retained the property of replacing p-aminobenzoic acid under the conditions where the latter was active (presence of serine or of glycine plus CO$_2$). Acid treatment of Leucovorin is known to result in a mixture of products (Cosulich, Roth, Smith, Hultquist & Parker, 1951), but further interpretation of the present results is not possible in view of the complexity of the chemical changes occurring during such treatment.

**Effect of glycine concentration on Leucovorin requirement.** The concentration of glycine required for growth (serine absent) with Leucovorin was almost identical with that required when growth was promoted by p-aminobenzoic acid plus CO$_2$ (Fig. 2); it was again about 50 times greater than that when serine was present. The concentration of glycine needed bore a reciprocal relation to the concentration of Leucovorin added (Fig. 5); a reduced quantity of glycine could be compensated (within limits) by increased Leucovorin. This effect is essentially similar to that observed earlier with CO$_2$ (Fig. 1a).

**Requirement for pyridoxal for growth on glycine.** The replacement of p-aminobenzoic acid by Leucovorin did not modify the absolute requirement for pyridoxal for growth (serine absent) with high concentrations of glycine (Table 4).

**Effect of Leucovorin on inhibition of growth by sulphathiazole.** The fact that Leucovorin replaces p-aminobenzoic acid for the growth of *Ln. mesenteroides* P60 suggests that the latter substance plays its part in cell metabolism through intermediate conversion to Leucovorin or a closely similar folic acid derivative. Since, however, the concentration of Leucovorin required was slightly higher than p-aminobenzoic acid, other interpretations were possible, and confirmation was sought by comparing the effects of the two factors on inhibition of growth by sulphathiazole on media containing either serine or high concentrations of glycine. There was, as anticipated, a strictly competitive relationship between p-aminobenzoic acid and the sulphonamide over a 1000-fold range of concentration of the latter (Fig. 6). With Leucovorin present (at just optimal concentration for growth), the organism was almost completely
insensitive to sulphathiazole, even at the highest concentration (Fig. 6). This would be expected if Leucovorin is the product of utilization of p-aminobenzoic acid whose formation is prevented by sulphonamide.

![Graph showing effect of Leucovorin concentration on glycine requirement](image)

**Fig. 5.** Effect of concentration of Leucovorin on the requirement for glycine (serine absent). Medium L plus $2 \times 10^{-7}$M-pyridoxal, $10^{-4}$M-p-aminobenzoic acid and the concentration (m) of Leucovorin shown on each curve. Incubation, 45 hr. in $N_2$.

![Graph showing ability of p-aminobenzoic acid and Leucovorin to overcome inhibition of growth by sulphathiazole](image)

**Fig. 6.** Ability of p-aminobenzoic acid and Leucovorin to overcome inhibition of growth by sulphathiazole. Medium L (charcoal-treated amino-acids) plus $2 \times 10^{-7}$M-pyridoxal and supplemented with either (a) $10^{-4}$M-serine + $5 \times 10^{-4}$M-glycine and incubated in $N_2$ (○, ●), or (b) $10^{-3}$M-glycine and incubated in 5% CO$_2$ in $N_2$ (○, ●). Leucovorin (Lv), --- ---; p-aminobenzoic acid (p-AB), ---.
The basal medium used in this work contained an amino acid mixture (except serine and glycine) and purines; the deduction that \( p \)-aminobenzoic acid functions through conversion to a Leucovorin-like substance can therefore only strictly be applied to its role in the synthesis of thymidine (results on serine medium) and in the conversion of glycine to serine (results on the high glycine medium).

**Serine content of organisms grown in serine-free medium**

It has been assumed in previous sections that when the organism grew in a serine-free medium containing high concentrations of glycine (with added \( CO_2 \) or Leucovorin) it was able to do so by synthesizing the required serine from glycine. This is a reasonable assumption in view of the likelihood that bacterial protein must contain serine in all circumstances. However, the matter was tested experimentally in the case of cells grown in glycine plus \( CO_2 \) by comparing their serine content with that of normal cells.

**Medium L** (no serine) was supplemented with \( 0.01M \)-glycine and the required amounts of \( p \)-aminobenzoic acid and pyridoxal for growth under these conditions. After inoculation the culture was incubated in 5\% \( CO_2 \) in \( N_2 \). To avoid any possible carry-over of serine, the inoculum was derived from the twelfth successive subculture of the organism on the same medium. The cells were harvested at full growth by centrifuging, and washed once in phosphate buffer. A sample of the final cell suspension was hydrolysed by heating in \( 6N \)-HCl in a sealed tube for 17 hr. at 105\(^\circ\). The hydrolysate was neutralized and assayed for serine by the microbiological assay described below. Control cells were derived from culture on a medium based on acid-hydrolysed casein (which contains serine) and were treated in the same way. The serine contents were (% serine of dry wt.): 0.9 for cells grown in glycine plus \( CO_2 \); 1.0 for the control cells. These are minimum values since some serine is known to be lost during acid hydrolysis. The interest here however is in the comparative rather than absolute contents.

The presence of serine in the hydrolysate was confirmed chromatographically after conversion to the dinitrophenyl derivative (Campbell \& Work, 1952). There is no doubt therefore that cells grown in the presence of glycine and \( CO_2 \) do, in fact, synthesize serine.

**The assay of serine**

It is clear from Fig. 3 that medium L is a suitable one for the assay of serine; thus with excess pyridoxal present the dose-response relationship is linear for the range 0.5 to \( 4 \times 10^{-5} \)M-L-serine. The preceding work has shown, however, that the presence of pyridoxal, glycine or Leucovorin-like substances in the material under test, or of \( CO_2 \) in the atmosphere, might seriously affect the validity of the assay.

**Effect of pyridoxal.** A valid assay would be obtained either with pyridoxal totally absent or present in excess. If the basal medium contains no pyridoxal (which is not essential for growth), any contribution of pyridoxal from the material under test would lead to erroneously high figures for serine (Fig. 3).
Nutrition of Leuconostoc mesenteroides P60

Excess pyridoxal (see Methods) should therefore be added for routine assays; it must be omitted, however, for special tests described later.

**Effect of glycine.** Even at the low concentration at which it is itself required for optimal growth, glycine increases growth with suboptimal serine, but only when the atmosphere contains CO₂ or when Leucovorin is present (Fig. 1b). If further glycine is added with the material assayed, this effect becomes more serious since the required concentration of CO₂ (Fig. 1a) or Leucovorin (Fig. 5) is then reduced, and growth may occur even in the absence of serine. For a valid assay it is therefore essential to remove Leucovorin or like substances from the test material and to make sure that the atmosphere of incubation does not become enriched with CO₂.

**Control of CO₂.** *Leuconostoc mesenteroides* P60 produces only traces of CO₂ during growth on medium L₄ and gives a homolactic fermentation of glucose (McCleskey, 1952; and present work). A sufficiently low concentration of CO₂ in the gas phase is attained by incubation of the tubes in a closed vessel filled with N₂ or H₂; the vessel should not however contain too many tubes. Incubation in air has sometimes been found to lead to erratic results. Although the normal CO₂ content of fresh air (0-08 %) would not interfere, the slightly higher content to be expected in a closed incubator containing other cultures may approach the critical level of 0-06 % effective with 10⁻²M-glycine (Table 2). Citrate, oxaloacetate and α-ketoglutarate are not normally likely to be present in material to be assayed at the high concentrations at which they replace CO₂. It is clear that a basal medium containing citrate cannot be used if the test material is likely to contain relatively large amounts of glycine.

**Removal of Ln. citrovorum factor.** Treatment of Leucovorin with dilute acid destroys its activity both for *Ln. citrovorum* (Broquist, Stokstad & Jukes, 1950) and in the present sense (Table 4). All material for assay should therefore be treated as in Exp. 2 of Table 4. It has been found, however, that complete removal is not certain when Leucovorin is added to bacterial extracts at concentrations exceeding 10⁻₆M. With each new type of material it is necessary to check (by specific assay with *Ln. citrovorum*) that this factor has been completely destroyed.

**Assay in the absence of pyridoxal.** When serine is absent, pyridoxal is essential for growth at any concentration of glycine even when CO₂ or Leucovorin is also present (Tables 2 and 4); serine, however, supports growth in the absence of pyridoxal. An assay in the absence of pyridoxal, even though less sensitive (Fig. 3), should always be used as a further check on the validity of results obtained as above. Pyridoxal is omitted from medium L₄ and the samples for assay treated to destroy members of the vitamin B₆ group. Steele et al. (1949), who had found these substances to stimulate growth of *Ln. mesenteroides* in the absence of serine, destroyed them by submitting materials for assay to ultraviolet irradiation. Pyridoxal can also be inactivated by autoclaving with tryptophan (Snell, 1945), and this method was used here. The experiment of Table 5 shows that the treatment is efficient and also results in no loss of serine. A solution of serine autoclaved with pyridoxal and tryptophan gave the same growth response as an untreated solution; the removal of
pyridoxal is shown by the fact that growth is halved when pyridoxal is absent from the assay medium (Table 5, cf. Fig. 3).

Table 5. *Destruction of pyridoxal by autoclaving with tryptophan*

A solution containing DL-serine \((10^{-3}\text{M})\), DL-tryptophan \((10^{-2}\text{M})\) and pyridoxal \((10^{-4}\text{M})\) was autoclaved at a pressure of 15 lb./sq.in. for 30 min. The treated solution was compared with DL-serine of equivalent molarity for its ability to support growth on medium L, with and without pyridoxal. Incubation: 44 hr. in air.

**DISCUSSION**

Glycine as precursor of serine. The fact that glycine (albeit at rather high concentrations) is able to replace serine under certain conditions for the growth of *L. mesenteroides* P60, and that cells grown in this way have a normal content of serine, provides strong evidence that this organism is able to convert glycine to serine. The possibility that glycine may be a normal intermediate in serine synthesis by micro-organisms has previously been suggested by observations that certain induced mutants of Neurospora and *E. coli* will grow if given either serine or glycine (Tatum, 1949; Roepke, Libby & Small, 1944; Wright, 1951). Further support for a direct origin of serine from glycine comes from a finding that, when *Torulopsis utilis* is grown on a medium containing [carboxy-\(^{14}\)C] glycine as sole source of carbon, the bulk of the isotope is found in the serine fraction of the hydrolysed cell-protein (Ehrensvärd, Sperber, Saluste, Reio & Stjernholm, 1947). In animal tissues Sakami (1948) has shown by isotope technique that C-2 of glycine is incorporated into C-2 of serine; C-3 of the latter may be derived from several methyl-group donors including formate and glycine itself (Sakami, 1948, 1949; Siegel & Lafaye, 1950).

Function of folic acid in the conversion of glycine to serine. The increased quantitative requirement for p-aminobenzoic acid (or Leucovorin) in growth under conditions where serine must be derived from glycine clearly indicates a specific function of folic acid at this step in serine synthesis. The ability of certain mixtures of amino acids and nucleic acid derivatives to replace the growth factor function of p-aminobenzoic acid and pteroylglutamic acid (and the anti-sulphonamide function of the former) had earlier suggested that
folic acid was required at some stage in serine formation (see reviews by Shive, 1951; Woods, 1952); serine was specifically implicated by Lampen, Jones & Roepke (1949) and Winkler & de Haan (1948) in the case of p-aminobenzoic acid and by Broquist & Snell (see Snell, 1951) in the case of pteroylglutamic acid. Wold & Sirny (1953) briefly reported that Leucovorin will replace serine for the growth of Ln. mesenteroides P60. Their basal medium contained glycine and citrate, and, as would be expected from the work reported here, supported some growth without added serine; the need for the latter was made absolute in their tests by increasing the concentration of L-alanine present. It was also mentioned that a relatively high glycine content increased growth in the serine-free medium.

A function of folic acid in the conversion of glycine to serine has received further indirect support from experiments with growing cultures of Lactobacillus bifidus (Nepple, Wright & Skeggs, 1951) and Tetrahymena pyriformis (geleii) (Kidder & Dewey, 1953). With the former organism folic acid would not replace serine unless glycine were present, while with the latter glycine replaced serine only when relatively high concentrations of folic acid were added. Evidence that the reaction promoted here by folic acid is one in which a one-carbon residue is transferred comes from Plaut, Bethel & Lardy (1950) who found that the incorporation of $^{14}$C from formate into C-3 of serine was markedly less in folic acid-deficient rats than in normal animals.

Metabolic relationship of p-aminobenzoic acid and Leucovorin. It has been seen that Leucovorin can replace p-aminobenzoic acid for the growth of Ln. mesenteroides P60; slightly higher molar concentrations of the former are required than would be expected simply on a basis of a 50% content of an inactive isomeride and a molecular equivalence with p-aminobenzoic acid. Nevertheless, the behaviour of the two growth factors in the presence of sulphonamide (Fig. 6) is in accord with that expected if Leucovorin (or a similar substance) is the sole product of the metabolism of p-aminobenzoic acid by the cell. Pteroylglutamic acid, however, is without activity either in replacing p-aminobenzoic acid or overcoming sulphonamide inhibition. Unless it be supposed that pteroylglutamate (though not the closely related Leucovorin) is unable to permeate the cell, a reasonable explanation of these results would be that this organism is able to convert either p-aminobenzoic acid or Leucovorin, but not pteroylglutamic acid, to the ultimate coenzyme form of folic acid; i.e. that pteroylglutamate is not a direct intermediate in the synthesis of the coenzyme.

Leuconostoc mesenteroides P60 is unique among organisms so far tested which require p-aminobenzoic acid, in that Leucovorin is active when pteroylglutamate is not. There is considerable variation among such organisms in the ability of pteroylglutamic acid to replace p-aminobenzoic acid and to render the organism insensitive to sulphonamides (Woods, 1950); but in all other cases the two forms of folic acid have both been either inactive or active for a given test organism (unpublished observations, see Woods, 1952). It would not be justifiable therefore to deduce from the present work either that Leucovorin is a normal intermediate in the synthesis of a coenzyme form of folic

Nutrition of Leuconostoc mesenteroides P60
acid, or that it is itself that coenzyme. These matters are discussed more fully elsewhere (Woods, 1952, 1953).

Requirement for vitamin B$_6$ in serine synthesis. Pyridoxal was found to be essential for growth whenever the organism was obliged to synthesize serine from glycine (Tables 2 and 4), though not when exogenous serine was supplied. It is probable therefore that this factor, presumably as pyridoxal phosphate, is also required for the glycine → serine transformation. Deodhar & Sakami (1953) briefly reported evidence that incorporation of [¹⁴C] formate into serine by chick tissues is dependent on vitamin B$_6$. Earlier work had also suggested that vitamin B$_6$ was needed at some stage in serine synthesis. *Strep. faecalis* R was found to require serine for growth (in an otherwise complete amino acid medium) only when pyridoxin was lacking, while growth of both *Lactobacillus arabinosus* and *Ln. mesenteroides* in the absence of this amino acid was stimulated by members of the vitamin B$_6$ group (Lyman, Moseley, Wood, Butler & Hale, 1947; Steele et al. 1949).

Although *Ln. mesenteroides* P 60 grew fully without addition of pyridoxal when serine was present, the concentration of this amino acid then required was double that needed when pyridoxal was also added (Fig. 8). No explanation has been found for this; since the same result was obtained with both DL- and L-serine the possibility that pyridoxal permitted the organism to use the D-isomer appears to be excluded. Vitamin B$_6$ derivatives are known to have such action with other amino acids, and pyridoxal phosphate has been shown to be the coenzyme of an alanine racemase enzyme system (Lyman & Kuiken, 1948; Wood & Gunsalus, 1951).

Effect of carbon dioxide. A more detailed analysis of the need for CO$_2$ or Leucovorin for growth with glycine (serine absent) will be published elsewhere and has been reported briefly (Cross, 1953). The inverse quantitative relationship between the required concentrations of glycine and CO$_2$ (Fig. 1a) led to the suggestion that CO$_2$ might serve, with growing cultures, as a source of the necessary one-carbon residue for condensation with glycine (Lascelles et al. 1951); later experiments with $^{14}$CO$_2$ have shown however that this is not the case. Leucovorin replaces CO$_2$ in this effect and there is again an inverse quantitative relationship with glycine. The quantity of serine found in the cells after growth in such conditions showed that it was impossible that the formyl group of Leucovorin itself was the ultimate source of the C-3 of serine; at least 200 molecules of serine were formed for each molecule of Leucovorin present at the time of inoculation.

We are grateful to Sir Rudolph Peters, F.R.S., for his interest in this work. One of us (M.J.C.) was indebted to the Ministry of Education for a grant for further education and training.
