Chemotaxonomic Study of an Alkalophilic Bacterium, 
Exiguobacterium aurantiacum gen. nov., sp. nov.

(Received 10 December 1982; revised 28 January 1983)

Chemical studies were performed on a Gram-positive alkalophilic bacterium of uncertain 
taxonomic position. On the basis of the present and earlier studies it is suggested that the 
alkalophilic bacterium be classified in a new genus Exiguobacterium, as Exiguobacterium 
aurantiacum gen. nov., sp. nov.

INTRODUCTION

The isolation of five strains of an alkalophilic bacterium from potato-processing effluent was 
reported by Gee et al. (1980). The bacterium was Gram-positive, non-sporing, facultatively 
aerobic and varied in shape from rods to almost coccoid forms. In some respects it resembled 
certain coryneform bacteria but its true taxonomic position was not determined (Gee et al., 
1980).

Recent improvements in the classification of coryneform and related bacteria have been 
made possible by analyses of cell wall peptidoglycan (Schleifer & Kandler, 1972), DNA base 
composition (Crombach, 1978) and lipid composition (Minnikin et al., 1978; Collins & Jones, 
1981). In the present study these techniques have been used to characterize further the 
alkalophilic bacterium of Gee et al. (1980) in an attempt to clarify its classification.

METHODS

Cultures and cultivation. For cell wall and lipid studies, five strains, BL77/1 to BL77/5, were cultivated in shake 
flasks of nutrient broth no. 2 (Oxoid) pH 7-8 at 30 °C for 3 d. Cultures were checked for purity, harvested by 
centrifugation (10000 g), washed with distilled water and freeze-dried.

Peptidoglycan analysis. The peptidoglycan type of two strains (BL77/1 and BL77/2) was determined as described 
by Schleifer & Kandler (1972). Purified walls were prepared from about 500 mg of dry cells, and the qualitative 
amino acid composition of the partial and complete wall hydrolysates was determined by paper chromatography. 
Quantitative determinations were made using an automatic amino acid analyser.

DNA base composition determinations. Strains BL77/1 and BL77/2 were grown to late-exponential phase, 
harvested by centrifugation and washed twice in distilled water. DNA was extracted and purified as described by 
Garvie et al. (1981). The DNA base composition was determined from its melting temperature in standard saline 
citrate as described by Garvie et al. (1981).

Analysis of polar lipids. Free lipids were extracted from dry organisms (50 mg) as described previously (Minnikin et al., 1979). Polar lipids were examined by two-dimensional thin-layer chromatography using HPTLC Kieselgel 
60F254 (Merck Art. 5628) plates (10 × 10 cm). Chromatograms were developed in the first dimension with 
chloroform/methanol/water (65:25:4, by vol.) and in the second dimension with chloroform/methanol/acetic 
acid/water (80:12:15:4, by vol.). Spraying with 10% (w/v) molybdophosphoric acid in ethanol followed by 
heating at 150 °C for 15 min revealed all the lipids present. Specific spray reagents for lipid phosphate (Dittmer &
**RESULTS AND DISCUSSION**

The purified peptidoglycan of strains BL77/1 and BL77/2 contained lysine as the dibasic amino acid. In addition alanine, glycine and glutamic acid were detected in the hydrolysates. Analysis of partial hydrolysates indicated the presence of a group A peptidoglycan (type Lysine-glycine) (Schleifer & Kandler, 1972). This peptidoglycan type has been reported previously in certain coryneform taxa (e.g. *Brevibacterium acetylicum*) and bifidobacteria (Schleifer & Kandler, 1972; Weiss et al., 1981). The peptidoglycan of strains BL77/1 and BL77/2 also resembles that of staphylococci, except that the latter normally have several glycine residues (i.e. Lysine-glycine$_{4-5}$; Schleifer & Kandler, 1972).

The DNA base composition of strains BL77/1 and BL77/2 was 53.4 and 53.2 mol % G + C respectively. The present result is lower than that reported (56 mol % G + C) for strain BL77/1 by Gee et al. (1980). A mol % G + C range of 53 to 54 is compatible with certain coryneform bacteria (see Table 1) but significantly higher than that reported for members of the genus *Staphylococcus* (Schleifer et al., 1979a, b). The mol % G + C range of 53 to 54 is also higher than that of most members of the genus *Bacillus*, although some *Bacillus* spp. possess DNA base ratios of 50 to 62 mol % G + C (Gibson & Gordon, 1974).

Components that co-chromatographed with vitamin K were the only isoprenoid quinones detected in the test strains (BL77/1 to BL77/5). UV absorption spectra of the purified quinones showed absorption maxima at 242, 248, 260, 269 and 325 nm, in accord with published data for menaquinones (Collins & Jones, 1981). The mass spectra of the menaquinone samples showed intense peaks at m/e 187 and 225 derived from the naphthoquinone nucleus with peaks in the high mass region (m/e 648, 580, 512; major component in bold) attributable to molecular ions (M$^+$). The major component corresponded to unsaturated menaquinones with seven isoprene units (abbreviated MK-7) although trace amounts of MK-6 and MK-5 were also present. The recovery of major amounts of MK-7 from the alkalophilic strains differentiates them from members of the 'coryneform group of bacteria' (Collins & Jones, 1981). Major amounts of MK-7 have however been reported to be present in a variety of other Gram-positive taxa (e.g. *Bacillus, Kurthia, Staphylococcus*) (Collins & Jones, 1981).

Diphosphatidylglycerol (DPG), phosphatidylglycerol (PG) and phosphatidylethanolamine (PE) were readily identified in the extracts of the test strains by their chromatographic behaviour and staining characteristics. In addition the test strains possessed minor amounts of an unidentified phospholipid (Fig. 1). No glycolipids were detected. The presence of PE in the test strains is of considerable interest. With the exception of a few mycolic acid-containing taxa (Minnikin et al., 1978) PE is not normally found in coryneform bacteria. Although PE is common amongst *Bacillus* species, the latter also possess glycolipids (Shaw, 1970; Lechevalier, 1977). It is worth noting that *Kurthia zopfii* also possesses the simple polar lipid pattern DPG, PG and PE (Goodfellow et al., 1980).

The results of the present study indicate that the alkalophilic bacterium of Gee et al. (1980) is quite distinct from all Gram-positive eubacteria examined to date (Table 1). The alkalophilic bacterium can be distinguished from all members of the 'coryneform group of bacteria' on the basis of cell wall peptidoglycan, mol % G + C, polar lipid and menaquinone composition. Although the alkalophilic bacterium resembles *Kurthia zopfii* in possessing a peptidoglycan based upon lysine, unsaturated menaquinones with seven isoprene units and a polar lipid composition comprising DPG, PG and PE, the former has a relatively low G + C content (about 37 mol %; Keddie, 1981). The alkalophilic bacterium can also be distinguished from the vast majority of *Bacillus* spp. on the basis of its cell wall composition. Members of the genus

Lester, 1964, x-glycols (Shaw, 1968), sugars (x-naphthol and anisaldehyde/H$_2$SO$_4$) (Jacin & Mishkin, 1965; Stahl & Kaltenbach, 1961) and free amino groups (ninyhdrin) were also used.

**Analysis of isoprenoid quinones.** Isoprenoid quinones were extracted from dry cells (50 mg) and purified as described by Collins et al. (1977). Purified quinones were further examined by reverse-phase partition chromatography as described previously (Collins et al. 1980b, 1982a). Mass spectra of the quinones were recorded on an AE1 MS9 instrument using a direct insertion probe, an ionizing voltage of 70 eV and a temperature range of 180 to 200 °C.

Fig. 1. Two-dimensional thin-layer chromatogram of polar lipids from strain BL77/1. Chloroform/methanol/water (65:25:4, by vol.) was used in the first dimension and chloroform/methanol/acetic acid/water (80:12:15:4, by vol.) in the second dimension. Abbreviations: DPG, diphosphatidylglycerol; PG, phosphatidylglycerol; PE, phosphatidylethanolamine; PL, unknown phospholipid.

Bacillus generally possess a directly cross-linked peptidoglycan based on meso-diaminopimelic acid (Schleifer & Kandler, 1972). Two alkalophilic bacilli, B. pasteurii and B. sphaericus, have however been reported to possess peptidoglycans based on lysine (Schleifer & Kandler, 1972). The DNA base compositions of B. pasteurii (42 mol % G + C) and B. sphaericus (37 to 43 mol % G + C) (Gibson & Gordon, 1974) are however incompatible with that of the alkalophilic bacterium (about 53 mol % G + C). Thus on the basis of phenetic (Gee et al., 1980), cell wall peptidoglycan, mol % G + C and lipid data, the alkalophilic bacterium appears to be quite distinct from all other Gram-positive taxa examined to date. We therefore propose that the alkalophilic bacterium of Gee et al. (1980) be classified in a new genus, Exiguobacterium (L. adj. exiguus short, small; Gr. neut. dim. n. bakterion a small rod; M.L. neut. n. Exiguobacterium small rod), as Exiguobacterium aurantiacum sp. nov.

Description of Exiguobacterium gen. nov.

Cells vary in shape from rods (3.2 × 1.2 μm) in the exponential phase to short, almost coccoid forms (1.4 × 1.1 μm) in the stationary phase (Gee et al., 1980). Both rods and coccoid cells are Gram-positive, non-acid fast and motile; endospores are not formed. The organism is facultatively anaerobic, catalase positive and oxidase negative. Acid is produced from glucose, sucrose, galactose and some other sugars. In anaerobic conditions with glucose as substrate, lactate, acetate and formate are major end products, the proportions depending on cultural conditions (Gee et al., 1980). The cell wall contains a group A type peptidoglycan based on lysine. Mycolic acids are not present. Menaquinones are the sole respiratory quinones; the principal quinone is MK-7. The major polar lipids consist of diphosphatidylglycerol, phosphatidylglycerol and phosphatidylethanolamine. The DNA base compositions of two strains are 53.2 to 55.8 mol % G + C. The type species is Exiguobacterium aurantiacum.

Exiguobacterium aurantiacum gen. nov., sp. nov.

Exiguobacterium aurantiacum (au.ran.ti.ac.um. L. neut. n. aurum gold; M.L. neut. n. Aaurantium generic name of the orange; M.L. neut. adj. aurantiacum orange-coloured).

Surface colonies on PPYG agar (Gee et al., 1980) are 2 to 3 mm in diameter after 3 d at 25 °C, low convex, orange, opaque, butyrous and easily emulsified. Colonies on heart infusion agar are normally flat and fainter orange. Orange pigment does not diffuse into medium; pigment production does not occur anaerobiically. Cells vary in shape from short, almost coccoid forms 1·4 × 1·1 μm in the stationary phase to rods 3·2 × 1·2 μm in the exponential phase (Gee et al., 1980). Longer, distorted rods may be formed during exponential growth at pH >10. Cells are Gram-positive, non-acid fast, non-spore-forming. Motile (peritrichous flagella). Growth occurs in aerobic and anaerobic conditions. Optimum temperature for growth (at pH 9·5) about 37 °C; temperature range of growth is from 7 to 43 °C; at 25 °C the pH range for growth is about 6·5 to 11·5, with two maxima, at pH 8·5 and pH 9·5 (Gee et al. 1980). Catalase positive, oxidase negative, glucose metabolized fermentatively. Acid produced from glucose, galactose, glycerol, maltose, mannitol and sucrose but not from L-arabinose, dulcitol, lactose, melezitose, raffinose, rhamnose, sorbitol or xylose. Acid sometimes produced from fructose and salicin. In anaerobic conditions with glucose as substrate, lactate, acetate and formate are the major end products, the proportions depending on cultural conditions. Starch, casein and gelatin are hydrolysed but not carboxymethylcellulose, dextran, pectin, tributyrin and Tween 80 are not attacked. Nitrate is reduced to nitrite. Growth is inhibited by chloramphenicol (10 μg per disc), erythromycin (10 μg), novobiocin (5 μg), oleandomycin (5 μg), penicillin G (1·0 μg) and tetracycline (10 μg) but not sulphasulphonylazole (100 μg).

The cell wall peptidoglycan is based on lysine (type Lysine-glycine,). Mycolic acids are not present. The principal isoprenoid quinone is MK-7. The major polar lipids consist of diphasatidylglycerol, phosphatidylglycerol and phosphatidylethanolamine. The G+C content of the DNA, determined by estimation of the melting point, is 53·2 to 55·8 mol % (Gee et al., 1980; present work). The type strain is NCIB 11798.
