The endolysins of bacteriophages CMP1 and CN77 are specific for the lysis of *Clavibacter michiganensis* strains

Johannes Wittmann, Rudolf Eichenlaub and Brigitte Dreiseikelmann

Department of Microbiology/Genetechnology, Faculty of Biology, University of Bielefeld, Universitaetsstr. 25, 33615 Bielefeld, Germany

Putative endolysin genes of bacteriophages CMP1 and CN77, which infect *Clavibacter michiganensis* subsp. *michiganensis* and *C. michiganensis* subsp. *nebraskensis*, respectively, were cloned and expressed in *Escherichia coli*. The His-tagged endolysin of CMP1 consists of 306 amino acids and has a calculated molecular mass of 34.8 kDa, while the His-tagged endolysin of CN77 has 290 amino acids with a molecular mass of 31.9 kDa. The proteins were purified and their bacteriolytic activity was demonstrated. The bacteriolytic activity of both enzymes showed a host range which was limited to the respective *C. michiganensis* subspecies and did not affect other bacteria, even those closely related to *Clavibacter*. Due to the high specificity of the CMP1 and CN77 endolysins they may be useful tools for biocontrol of plant-pathogenic *C. michiganensis* without affecting other bacteria in the soil.

INTRODUCTION

The genus *Clavibacter* is a member of the Microbacteriaceae, a group of Gram-positive bacteria of high G+C content that can be distinguished from other groups among the Actinobacteria by the unusual peptidoglycan type B and unsaturated respiratory menaquinones (Park *et al.*, 1993). The plant-pathogenic bacterium *Clavibacter michiganensis*, the only species in the genus *Clavibacter*, includes five subspecies which are defined with respect to their host plants: subsp. *michiganensis* (*Solanum lycopersicum*), *nebraskensis* (*Zea mays*), *insidiosus* (*Medicago sativa*), *tessellarius* (*Tritium aestivum*) and *sepedonicus* (*Medicago truncatula*) (Davis *et al.*, 1984; Lee *et al.*, 1997; Eichenlaub *et al.*, 2007).

*C. michiganensis* subsp. *michiganensis* (*Cmm*) causes bacterial wilt and canker, the most important bacterial disease of tomato, which results in severe crop failures in all tomato-growing areas worldwide (Strider, 1969). Control of *Cmm* infections is difficult because there are neither resistant tomato cultivars nor effective chemical-based approaches available. Thus, the spread of *Cmm* infections can only be limited by using certified seeds, strict hygiene measures and eradication of infected plants.

Based on problems with antibiotic resistance of human and animal pathogenic bacteria and on the lack of effective antibacterial compounds for disease control in plants, the interest in bacteriophages for therapy of bacterial infections has increased during the last few years. To date, there are many examples of the application of bacteriophages in disease control of humans, animals and plants (Sulakvelidze & Barrow, 2005; Sulakvelidze & Kutter, 2005; Jones *et al.*, 2007). In agriculture, phages have been successfully used, e.g. against soft rot and fire blight caused by *Erwinia* spp. (Eayre *et al.*, 1990; Schnabel *et al.*, 1998), tomato bacterial spot caused by *Xanthomonas* spp. (Balogh & Jones, 2003) and tobacco bacterial wilt caused by *Ralstonia solanacearum* (Tanaka *et al.*, 1990).

Disease control with the help of bacteriophages can be achieved either with the bacteriophages themselves or with phage-encoded bactericidal enzymes (Parisien *et al.*, 2008). Since it is difficult to treat large agricultural areas with an enzyme formula it seems more suitable to use the genes for lytic enzymes of bacteriophages for the generation of transgenic plants. The endolysins of tailed bacteriophages, which are synthesized in infected bacteria late in the lytic cycle for the release of the progeny phages, are good candidates for this purpose and have a high potential for application in therapy and disease control, because of their diversity and specificity (Fischetti, 2008; Loessner, 2005). A high efficiency in lysis of the pathogenic bacteria and specificity for the host are prerequisites for an application in the prevention and/or treatment of bacterial infections.

Abbreviations: *Cmm*, *Clavibacter michiganensis* subsp. *michiganensis*; *Cmn*, *C. michiganensis* subsp. *nebraskensis*; *Cmt*, *C. michiganensis* subsp. *tessellarius*; DAB, dianisobutyric acid; NTA, nitrilotriacetic acid.

The GenBank/EMBL/DDBJ accession numbers for the complete genome sequence of phage CMP1 and for the CN77 *Small* restriction fragment are GQ241246 and GU978892, respectively.

A supplementary table, showing the results of a lysis assay with CMP1 endolysin on different Microbacteriaceae strains, is available with the online version of this paper.
The search for an endolysin specific for Cmm seems promising because the peptidoglycan type B2γ is not very frequent among bacteria (Schleifer & Kandler, 1972). The type B2γ peptidoglycan is defined by a cross-linkage between positions 2 and 4 of the peptide subunits (B), a D-diamino acid in the interpeptide bridge (B2) and L-diaminobutyric acid (DAB) at position 3 of the peptide subunit (B2γ). A further advantage is that Gram-positive bacteria are easy to lyse by an enzyme from the outside since they have no outer membrane.

This study mainly focuses on the endolysin of bacteriophage CMP1 of Cmm first described by Echandi & Sun (1973). The endolysin of CN77, a phage with the host C. michiganensis subsp. nebraskensis (Cmm) (Cook & Katzenelson, 1960; Shirako et al., 1986; Vidaver et al., 1981), was included in the study in order to increase the chance of finding a highly specific enzyme.

METHODS

Bacterial strains and phages. Bacteriophage CMP1 was a gift from E. Echandi, North Carolina State University (Echandi & Sun, 1973). Bacteriophage CN77 was from the Felix D’Herelle Reference Center for Bacterial Viruses, Université Laval (Canada). For the propagation of the phages, the host strains Cmm NCPPB3123 and Cmm Her1088 (Université Laval) were incubated with shaking in TBY (per litre: 10 g tryptone, 5 g yeast extract, 5 g NaCl, pH 7.5) at 26 °C until a titre of 3 x 10^10 c.f.u. ml^-1 reached. After infection with phages at an m.o.i. of 0.1, incubation was continued at room temperature without shaking until lysis was complete (about 15–20 h). The lysate was cleared by centrifugation.

Expression of the endolysin genes was done in Escherichia coli ArcticExpress [E. coli B, F-, ompT, hsdRb, gal, ι(DE3)], endA Hte (cnn10, cnn60, Gent') (Stratagene).

The Microbacteriaceae and further Gram-positive bacteria used for the activity assays are listed in Supplementary Table S1. The strains Cmm 2-7, 4-4, 9-4, S-5 and S-7 were isolated from infected tomato plants from the island of Reichenau (Germany); the strains Cmm 18, 24, 42, 48, 56 and 64 were a gift from S. Manulis-Sasson and were isolated at different places in Israel (Volcani Center, Bet Dagan, Israel; Kleitman et al., 2008). The C. michiganensis subspecies were from the National Collection of Plant Pathogenic Bacteria (NCPBP), Laboratorium voor Microbiologie (LMG; Ghent, Belgium) and ATCC collections.

Purification of phages and phage DNA. Purification of the phages by CsCl gradient centrifugation and of the DNAs by phenol extraction was done as previously described (Beilstein & Dreiseikelmann, 2006).

PCR amplification and cloning of the endolysin genes. After determination of the phage DNA sequences, primers could be generated for the amplification of the lys genes. The forward primers carried an NdeI recognition site and the reverse primers a XhoI recognition site at the 5′ ends. The PCR mixtures contained phage DNA as target, dNTPs, polymerease Pwo (Peqlab), the corresponding reaction buffer (Peqlab) and the primer pairs 5′-CGCATATGG-CCGGAGAATCTTAAC-3′ and 5′-CTTGTGTTTCTATCGGCGG-3′ for the CMP1 endolysin gene amplification, and 5′-CGCATATGG-GCTACTGGGGGT-3′ and 5′-CGCTCGAGTGCGGAGCTCCCG-3′ for the CN77 gene amplification. Amplification was done with a gradient cycler (Stratagene). PCR conditions were one cycle of 10 min at 95 °C; followed by 35 cycles of 90 s at 95 °C, 90 s at an annealing temperature between 50 and 66 °C, 90 s at 72 °C, and one final cycle of 10 min incubation at 72 °C. The PCR products were hydrolysed with restriction endonucleases NdeI and XhoI and ligated with pSCodon1.2 (Eurogentec) digested with the same enzymes. The main features of this vector are a T7 promoter, six his codons (for a C-terminal His-tag) and genes for five rare tRNAs. E. coli ArcticExpress (Stratagene) was transformed with the hybrid pSCodon1.2_lys plasmids by the CaCl₂ method. Selection of transformed cells was done on TBY agar plates with ampicillin (150 µg ml^-1) and gentamicin (10 µg ml^-1).

Expression and identification of the endolysins. E. coli ArcticExpress pSCodon1.2_lys_CMP1 or pSCodon1.2_lys_CN77 was grown in TBY medium with ampicillin (150 µg ml^-1) and gentamicin (10 µg ml^-1) at 26 °C to a titre of about 4 x 10^9 c.f.u. ml^-1. The culture was cooled down. After addition of 1 mM IPTG, incubation was continued with shaking at 12 °C for 15 h. Overproduction of endolysin was monitored by SDS-PAGE of total cell protein recovered after boiling of the cells in cracking buffer (Laemmli, 1970; Lanka & Barth, 1981). For the identification of soluble proteins, supernatants of centrifuged French Press extracts were used for electrophoresis.

Isolation of the endolysin. Sedimented cells from a 200 ml induced culture were frozen at −80 °C. After thawing, the cells were suspended in 3 ml buffer A (50 mM sodium phosphate buffer, pH 7.8, 300 mM NaCl, 10 mM β-mercaptoethanol). Cells were lysed by three passages through the French pressure cell at 124 200 kPa. The lysate was cleared by centrifugation for 30 min at 25 000 g. The supernatant was centrifuged again and applied to a Ni-nitrilotriacetic acid (NTA; Qiagen) column (bed volume 0.4 ml) equilibrated with buffer A. After washing with buffer B and buffer A with 20 mM imidazole, elution was done with a linear gradient of 50–400 mM imidazole in buffer A (5 ml). Samples of each fraction (0.5 ml) were analysed by SDS-PAGE and by an activity assay.

Endolysin assays. Endolysin activity was assayed with sterile filtered cleared lysates from induced E. coli cells in comparison with cleared lysates from cells containing pSCodon1.2 without insert DNA and with fractions from the Ni-NTA chromatography. TBY agar plates were overlaid with 150 µl overnight culture of the indicator strain in 3 ml top agar (0.5% agar in TBY). Drops of endolysin samples were placed onto the surface and plates were incubated at 26 °C. For a rapid screening of many indicator strains these were streaked from a master plate to a fresh TBY plate, and 10 µl drops of endolysin samples were layered on the streaks. In addition, the decrease of the OD_600 from an exponential phase culture (OD_600 = 1.0) after addition of endolysin-containing fractions [20 µl extract (ml indicator culture)^-1] was monitored at room temperature.

SDS-PAGE and immunoblotting. SDS-PAGE was performed by the method of Laemmli (1970). All gels contained 17.5% (w/v) acrylamide and were stained with Coomassie brilliant blue R-250. Total cell protein was recovered from induced cells after boiling of the cells in cracking buffer (Lanka & Barth, 1981).

Immunoblot analysis was done as previously described (Disqué-Kochem & Dreiseikelmann, 1997) with a primary monoclonal anti-His antibody (mouse, Abcam) and a secondary alkaline phosphatase-coupled antibody (goat anti-mouse, Abcam).

Xylem sap collection. Four-week-old tomato plants (S. lycopersicum cv. Moneymaker) were cut about 2 cm above the ground. The exudates were collected from the stumps for about 30 min.

Bioinformatic analyses. NCBI programs BLASTp, PSI-BLAST (non-redundant database) and Conserved Domains were used for similarity and domain searches of the putative proteins (Altschul et al., 1997).
Microbiology

L-Ala and D-Glu residues, are also members of the M15 superfamily of DD-carboxypeptidases (pfam02557, E-value 4e-14) for the CN77 endolysin. According to the MEROPS peptidase database revealed that the active site of a putative zinc metalloprotease. The amino acid residues H86, D93, E120 and H123 may represent the hypothetical CMP1 endolysin belongs to the M15 family of mostly specialized metalloproteases. The amino acid residues H86, D93, E120 and H123 may represent the active site of a putative zinc metalloprotease. The endolysins of Listeria monocytogenes bacteriophages A118 and A500, which cleave the cell wall peptidoglycan between L-Ala and D-Glu residues, are also members of the M15 peptidase family (Loessner et al., 1995).

The ORF downstream of the putative CMP1 lys gene may encode a small protein of 108 amino acid residues with three predicted transmembrane helices, which strongly indicates that it functions as a class I holin (Young & Bla¨si, 1995). The proximity of the putative holin gene was further evidence that the upstream gene may encode an endolysin, because these two genes that function in the release of progeny phages are mostly clustered at the 3’ end of the late genes. Holins function in the timing of lysis. They are located in the cytoplasmic membrane and are required for the export of the active endolysin at a genetically determined time to allow its access to the peptidoglycan.

The identification of the endolysin gene of bacteriophage CN77 and its deduced amino acid sequence of 290 amino acid residues and a molecular mass of 31.9 kDa was much easier. In contrast to the CMP1 enzyme, PSI-BLAST analysis predicted a highly conserved domain of the VanY superfamily of DD-carboxypeptidases (pfam02557, E-value 4e-14) for the CN77 endolysin. According to the MEROPS database, the CN77 enzyme also belongs to the M15 family of metalloproteases.

RESULTS AND DISCUSSION

Bioinformatic analysis of the putative lys genes of CMP1 and CN77 and their deduced amino acid sequences

The annotation of a putative endolysin gene on the CMP1 genome (58 652 bp; results not shown) was based on several observations. The ORF is located between nucleotides 35 449 and 36 369 at the end of a cluster of genes that are expressed late in the lytic cycle. The deduced amino acid sequence is 306 aa long with a calculated molecular mass of 34.8 kDa. This agrees well with the size of endolysins from other phages that infect Gram-positive bacteria, which have a typical molecular mass of 25–40 kDa (Fischetti, 2008).

Analysis of the amino acid sequence with PSI-BLAST revealed a weak similarity of the N-terminal part to a DD-carboxypeptidase of Stigmatella aurantiaca (identities 29/79, 36 %) and Myxococcus xanthus (identities 27/73, 36 %); conserved domains were not indicated. Further analysis with the MEROPS peptidase database revealed that the hypothetical CMP1 endolysin belongs to the M15 family of mostly specialized metalloproteases. The amino acid residues H86, D93, E120 and H123 may represent the active site of a putative zinc metalloprotease. The endolysins of Listeria monocytogenes bacteriophages A118 and A500, which cleave the cell wall peptidoglycan between L-Ala and D-Glu residues, are also members of the M15 peptidase family (Loessner et al., 1995).

The ORF downstream of the putative CMP1 lys gene may encode a small protein of 108 amino acid residues with three predicted transmembrane helices, which strongly indicates that it functions as a class I holin (Young & Bla¨si, 1995). The proximity of the putative holin gene was further evidence that the upstream gene may encode an endolysin, because these two genes that function in the release of progeny phages are mostly clustered at the 3’ end of the late genes. Holins function in the timing of lysis. They are located in the cytoplasmic membrane and are required for the export of the active endolysin at a genetically determined time to allow its access to the peptidoglycan.

The identification of the endolysin gene of bacteriophage CN77 and its deduced amino acid sequence of 290 amino acid residues and a molecular mass of 31.9 kDa was much easier. In contrast to the CMP1 enzyme, PSI-BLAST analysis predicted a highly conserved domain of the VanY superfamily of DD-carboxypeptidases (pfam02557, E-value 4e-14) for the CN77 endolysin. According to the MEROPS database, the CN77 enzyme also belongs to the M15 family of metalloproteases.

Since the peptidase domains of the CMP1 and CN77 endolysins are located in the N-terminal part of the protein, they may have a modular structure consisting of an N-terminal catalytic domain and a C-terminal substrate-binding domain, as described for other endolysins (Garcia et al., 1990; Fischetti, 2008). Neither enzyme showed extensive amino acid sequence similarity to the other. While no similarity was detected between the N-terminal catalytic domains, a moderate similarity was found between the C-terminal binding domains (identities=39/127; 30 %).

Overexpression of the putative lys genes and isolation of the gene products

The lys PCR products of CMP1 and CN77 were ligated with the vector pSCodon1.2. After transformation of E. coli ArcticExpress with the hybrid plasmids, induction of the cells was performed with 1 mM IPTG for 15 h at 12 °C (Fig. 1). The host strain ArcticExpress allowed an efficient folding of proteins after induction at 12 °C due to the co-expression of the cold-adapted chaperonins Cpn10 and Cpn60 of Oleispira antarctica. Induction with 1 or 0.1 mM IPTG and incubation at 37 and 22 °C in the absence of the chaperonins resulted in the formation of inclusion bodies (data not shown).

After electrophoretic separation of crude extracts from whole cells in an SDS-polyacrylamide gel, moderate

overproduction of proteins corresponding to the calculated molecular mass of the endolysins was visible (Fig. 1a, c). The His-tagged proteins were purified from crude extracts by Ni-NTA chromatography. Fractions of the CMP1 endolysin eluted with imidazole are shown in Fig. 1(a) (lanes 4–6), and those of the CN77 endolysin in Fig. 1(c) (lanes 9–11). The main part of the proteins eluted from the column with 100–200 mM imidazole. The Coomassie blue-stained SDS-PAGE showed that the CN77 enzyme was still contaminated with some smaller proteins, but there was only one signal in the immunoblot (Fig. 1b, lane 8). In Ni-NTA fractions of the CMP1 enzyme only one protein of about 16 kDa could be detected which coeluted with the CMP1 endolysin at about 35 kDa. The small protein was already visible as a strong band in the total protein extract of induced cells (Fig. 1a, lane 2). In the immunoblot analysis this protein reacted with the anti-His antibody, suggesting that it was the C-terminal part of the endolysin (Fig. 1b, lane 7). MALDI-TOF analysis confirmed that the larger protein was the endolysin while the smaller one represented the C-terminal part of the enzyme (data not shown).

Examination of the nucleotide sequence of the CMP1 endolysin gene revealed a possible Shine–Dalgarno sequence within the gene four nucleotides upstream from an ATG codon in-frame of the gene (Fig. 2). A hypothetical gene product would consist of the 166 C-terminal amino acid residues of the CMP1 endolysin and represent the binding domain of the enzyme. After deletion of an NdeI–MfeI DNA fragment from the expression plasmid pSCodon1.2_Lys_CMP1, overproduction of a protein could be observed with a molecular mass corresponding to the small protein that coeluted with the full-length endolysin (data not shown). It is not known whether the speculated translational restart in *E. coli* also occurs in *Clavibacter*. Until now there has been no example of the separate expression of a binding domain of an endolysin in addition to the complete enzyme.

**Activity of the endolysins**

The enzymic activity of the putative endolysins was assayed by a spot test on agar plates with an indicator strain. Drops of cleared lysates from induced *E. coli* cultures harbouring the plasmids pSCodon1.2_Lys_CMP1 and pSCodon1.2 were placed on agar plates inoculated with the host strain. Fig. 3 shows the lysis zones on a *Cmm* indicator lawn caused by the CMP1 and CN77 endolysins, while the control extract showed no effect. 'Lysis zones' were also obtained with purified protein from the Ni-NTA chromatography (data not shown). In this assay it cannot be distinguished whether the 'lysis zones' in the bacterial lawns resulted from lysis or from growth inhibition.

To verify the lytic activity of the CMP1 and CN77 proteins, exponential phase cultures of indicator strains (*Cmm* NCPPB3123, *Cmm* NCPPB7173 and *C. michiganensis* subsp. *tessellarius* (*Cmt*) NCPPB7295; OD$_{600}$~1) were exposed to extracts prepared from endolysin-containing *E. coli* cells. Crude extracts were preferred because the purification of the enzymes resulted in a significant loss of activity. The decrease of the optical density in comparison with extracts without endolysin clearly demonstrated that the cells were lysed by the bacteriophage endolysins (Fig. 4). The CMP1 endolysin exhibited the highest efficiency with *Cmm* cells (Fig. 4a) and the CN77 enzyme with *Cmn* cells (Fig. 4b), which means that the hosts of the bacteriophages are the optimal substrates. *Cmt* cells are insensitive to the CMP1 endolysin and are poorly lysed by the CN77 endolysin.

Besides differences in their specificity towards different *Clavibacter* subspecies the enzymes also showed different pH optima. While the CMP1 enzyme showed the highest activity at a neutral pH of about 7, the CN77 enzyme had a pH optimum of about 8–9 (Fig. 5). Both enzymes showed
significant activities in slightly acidic buffers between pH 5 and 7.

Activity in an acidic milieu is a prerequisite for the use of the CMP1 endolysin produced from a transgenic tomato plant for protection against \textit{Clavibacter} infections, as the pH of the tomato xylem fluid is about 5.5–6.0 (White et al., 1981). To analyse whether the CMP1 endolysin is active in xylem sap, \textit{Cmm} cells were sedimented and resuspended in freshly prepared xylem sap from 4-week-old tomato plants. After addition of the enzyme-containing extract, the decrease in OD$_{600}$ was monitored (Fig. 6). The enzyme was active in xylem sap, but the activity was reduced in comparison with the activity in buffer at pH 5.7, the pH determined for xylem sap.

**Host specificity of CMP1 and CN77 endolysins**

Assuming a future application of the endolysins in plant protection it is necessary to determine the host specificity. For ecological reasons an enzyme with a high degree of specificity would be preferred. In summary, 46 strains with different cell wall types were screened for lysis after spotting a CMP1 and CN77 endolysin-containing extract onto streaks of the strains on agar plates. All strains are listed in Supplementary Table S1 and the most important ones in Table 1. All five subspecies of \textit{C. michiganensis} were lysed by the endolysins, with the exception of the subspecies \textit{tessellarius}, which was not lysed by CMP1.

![Fig. 4. Lysis of different \textit{Clavibacter} strains by CMP1 (a) and CN77 (b) endolysins. A 20 µl volume of crude extract from induced cells expressing the lysin was added to 1 ml of a culture of \textit{Cmm} NCPPB3123 (●), \textit{Cmn} NCPPB7173 (■) and \textit{Cmt} NCPPB7295 (▲) (in TBY medium, initial OD$_{600}$ ~1.0). As a negative control, crude extracts from induced cells without endolysin genes were added to the cultures (Cm$^-$; ○). The decrease in OD$_{600}$ was monitored every 3 min for 15 min.](image)

A 1 ml volume of indicator cells (\textit{Cmm} NCPPB3123 for CMP1 endolysin, \textit{Cmn} NCPPB7173 for CN77 endolysin) at initial OD$_{600}$ ~1.0 was sedimented by centrifugation and resuspended in 1 ml 50 mM Tris/HCl of various pHs, 50 mM NaCl, 5 mM β-mercaptoethanol. A 20 µl volume of crude lysate from induced cells expressing the lysins was added. The decrease in OD$_{600}$ was monitored every 3 min for 15 min. The figure shows the amount of lysed cells 6 min after the addition of the enzymes.](image)

![Fig. 6. Activity of CMP1 endolysin in xylem sap. A 1 ml volume of indicator cells (\textit{Cmm} NCPPB3123) with initial OD$_{600}$ ~1.0 was sedimented by centrifugation and resuspended in 1 ml 50 mM Tris/HCl, pH 5.7, 50 mM NaCl, 5 mM β-mercaptoethanol (■) or freshly prepared xylem sap (▲). A 20 µl volume of crude lysate from induced cells expressing the lysins was added. The decrease in OD$_{600}$ was monitored every 3 min for 15 min. The figure shows the amount of lysed cells 6 min after the addition of the enzymes. As a control, OD$_{600}$ was determined for cells without addition of endolysin (□).](image)
endolysin (as shown in Fig. 4). The cell wall of the species 
*C. michiganensis* has been determined to be type B2γ, 
which contains D- and L-2,4-DAB as a diamino acid (Sasaki 
et al., 1998; Schleifer & Kandler, 1972). So far, there is no 
information on whether the murein type of the subspecies 
tessellarius differs from that of the other subspecies. The 
determination of the enzyme cleavage site would help us to 
learn more about the structure of the peptidoglycan of the 
*C. michiganensis* subspecies. To show that the enzymes lyse 
different Cnm strains, 11 environmental Cnm isolates 
from Germany and Israel (not shown in Supplementary 
Table S1) were tested and were lysed by both enzymes, 
demonstrating that the enzymes are generally active 
towards Cnm. The same result was obtained with Cnm 
strains. Besides the CN77 host strain Her1088, nine 
aditional Cnm strains from the NCPPB collection were 
screened. All strains were lysed by the CMP1 and CN77 
endolysins.

As far as is known, the only other species with the same 
peptidoglycan type as *Clavibacter*, type B2γ, containing D- 
and L-DAB, are members of the genus *Leifsonia* 
(Evtushenko et al., 2000). Nevertheless *Leifsonia aquatica* 
was not lysed by the endolysins of phages CMP1 and 
CN77. This suggests that the peptidoglycans of *Clavibacter* 
and *Leifsonia* are not identical but may contain some 
minor modifications not yet determined. Further species 
closely related to *C. michiganensis*, such as the plant 
pathogen *Rathayibacter* sp., which was separated from the 
*Clavibacter* group several years ago, are not affected by the 
enzyme (Sasaki et al., 1998). Like *Clavibacter*, the genus 
*Rathayibacter* has a peptidoglycan of type B2γ, but it 
contains only L-DAB. Five environmental isolates which 
were also not lysed by the endolysins. They have different 
peptidoglycan types such as B2α, B2β and B1α (Table 1). 
Therefore, it was not surprising that Gram-positive strains 
such as *Bacillus subtilis*, *Bacillus megaterium*, *Enterococcus 
aeacalis*, *Staphylococcus aureus*, *Micrococcus luteus* and 
*Corynebacterium glutamicum*, which all have a type A 
peptidoglycan (cross-linkage between position 3 and 
position 4 of the adjacent peptide; Schleifer & Kandler, 
1972), and Gram-negative strains were not affected by the 
enzymes. Thus, the activity of the bacteriophage CMP1 and 
CN77 endolysins is limited to *C. michiganensis* subspecies 
and they do not even lyse other related species of the 
*Microbacteriaceae*.

In this communication we demonstrate that the products 
of the *lys* genes from bacteriophages CMP1 and CN77 
encode active and highly specific endolysins. The enzymes 
lyse strains of *C. michiganensis* from the outside by 
hydrolysis of the murein sacculus. This renders the 
bacterial cells osmotically unstable and finally leads to cell 
death. So far we have not found any Gram-negative or 
Gram-positive bacterium other than *C. michiganensis* that 
is lysed by the enzymes, underlining the specificity of the 
enzymes for the type B2γ cell wall. Thus, the application of 
these enzymes in biocontrol of *Cnm* would be unlikely to 
affect the bacterial community in the soil or other bacteria 
associated with the plant, which may have a beneficial 
effect on plant growth. In the next step of this project we 
plan to express the endolysins in tomato plants.

Infection of tomato plants usually occurs by wounds in the 
root or stem section of the plant. Therefore, the spread of 
infection is particularly caused by the pruning of tomato 
plants. A tomato plant that expresses the endolysin may

**Table 1.** Lysis assay with CMP1 endolysin on different *Microbacteriaceae* strains

*Environmental isolates (K.-H. Gartemann, Universität Bielefeld, Germany).
inhibit the invasion of Cmm into the wounded tissue and thus may prevent a successful infection by Cmm.

ACKNOWLEDGEMENTS

We thank S. Manulis-Sasson, ARO, Bet Dagan, Israel, and K. H. Gartemann, Universität Bielefeld, Germany, for providing us with strains from their collections.
