(Accepted for publication 19 April 1972)

Phosphate regulation of baker's yeast acid phosphatase (EC. 3.1.3.2) has been reported by several authors (Suomalainen, Linko & Oura, 1960; Heredia, Yen & Sols, 1963; McLellan & Lampen, 1963; Schmidt et al. 1963; Günther & Kattner, 1968; Schurr & Yagil, 1971). In this work the formation of acid phosphatase in baker’s yeast during growth in culture media differing in either KH₂PO₄, β-glycerophosphate or phenylmercuric acetate (PMA) content was studied.

METHODS

Commercial baker’s yeast (‘Pliva’, Zagreb) or Saccharomyces cerevisiae strain 218 (Technological Faculty Collection, Zagreb) was used. A modification of the medium described by Bandyopadhyay & Humphrey (1967) was used for cultures. It was a ‘low-phosphate’ medium containing 15 mg of phosphorus/l and was free of orthophosphate. This ‘low-phosphate’ medium was supplemented with 0.5 mM and 1 mM-KH₂PO₄ or with 0.5 mM and 1 mM-β-glycerophosphate. When the organisms were grown in the presence of PMA the medium was orthophosphate-free or contained either 1 mM or 10 mM-KH₂PO₄. The organisms were grown aerobically with agitation in 100 ml batches at 28 °C for 12 to 18 h.

Cell-free extracts were obtained from suspensions in succinate buffer at pH 3·5 using a Braun mechanical cell homogenizer (model MSK, type 853030). The supernatant obtained after centrifuging at 96000 g was used as the cell-free extract. Acid phosphatase activity was assayed according to Torriani (1960). Phosphorus was determined by the method of Chen, Toribara & Warner (1956).

RESULTS

It was found that formation of acid phosphatase in yeast cells was dependent on the initial concentration of KH₂PO₄ or β-glycerophosphate in the culture medium (Fig. 1). Yeast grown in a ‘low-phosphate’ medium exhibits a relatively high activity of acid phosphatase. When, after 10 h of cultivation, KH₂PO₄ (0·5 mM or 1 mM) was added, repression of acid phosphatase took place (see insert to Fig. 1).

It has been recently reported (Schurr & Yagil, 1971) that KH₂PO₄ inhibits competitively yeast acid phosphatase. Kinetic studies performed in our laboratory revealed that KH₂PO₄ is a competitive inhibitor of acid phosphatase in the living cells of commercial baker’s yeast and in a cell-free extract, with a Kᵢ value of 2·4 × 10⁻³ M. In our experiments total inhibition was achieved with 0·1 mM-KH₂PO₄. The activity of acid phosphatase in phosphate-treated cells was completely restored after washing the cells with water.

Fig. 1. Repression of acid phosphatase by phosphate. Acid phosphatase activity in yeast cells during cultivation at two different concentrations of KH$_2$PO$_4$ ($\triangle$, 0.5 mM; $\bullet$, 1 mM) or $\beta$-glycerophosphate (○, 0.5 mM; ●, 1 mM). The activity of acid phosphatase of cells grown in the 'low-phosphate' medium was taken as 100%. The insert shows the activity of acid phosphatase during growth in the 'low-phosphate' medium (□), and its repression after the addition of KH$_2$PO$_4$ ($\triangle$, 0.5 mM; $\bullet$, 1 mM).

Interaction of PMA with yeast acid phosphatase has been reported (Ries & Suomalainen, 1970). It was shown that 10$^{-3}$ M-PMA inhibits the yeast acid phosphatase when added to the assay mixture. In our experiments PMA was added to the growth medium as well at concentrations of 10$^{-6}$, 10$^{-8}$, 10$^{-7}$, 10$^{-8}$ and 10$^{-9}$ M. It was found that growth was inhibited if the medium contained more than 10$^{-7}$ M-PMA.

In a series of experiments the yeast was cultivated in 10$^{-7}$ M-PMA for 18 h in 'low-phosphate' medium and media containing either 1 mM or 10 mM-KH$_2$PO$_4$ and the acid phosphatase activities of the cells determined. PMA (10$^{-7}$ M) induced acid phosphatase; the highest induction was obtained in the medium containing 1 mM-phosphate.

Yeast grown in 10$^{-7}$ M-PMA responded differently to 10$^{-3}$ M-PMA added to the assay mixture dependent upon the phosphate concentration of the medium. In 'low-phosphate' medium, only 28% enzyme activity was retained in the presence of 10$^{-3}$ M-PMA, whereas in the medium containing 1 mM-phosphate, acid phosphatase retained 70% of its activity. There was no inhibition of acid phosphatase by 10$^{-3}$ M-PMA if the medium contained 10 mM-KH$_2$PO$_4$, although at this concentration of orthophosphate the enzyme activity was low.
DISCUSSION

The level of acid phosphatase in baker’s yeast is influenced by the concentration of the phosphate in the culture medium. When β-glycerophosphate was the only source of phosphate, acid phosphatase was not repressed initially to the same extent as when KH₂PO₄ was used. This observation could be explained by assuming a gradual liberation of the phosphate from the organic ester into the medium. Subsequent addition of KH₂PO₄ to ‘low-phosphate’ medium quickly represses the enzyme.

Phosphate inhibited competitively acid phosphatase in the assay mixture. The fact that phosphate could be removed by washing indicates a high dissociation constant for the phosphate-enzyme interaction.

Acid phosphatase of yeast grown in ‘low-phosphate’ medium, was inhibited by 10⁻³ M-PMA in the assay mixture. Increasing the concentration of phosphate decreased the inhibition. Apparently the yeast grown in phosphate-sufficient medium can counteract the action of PMA more efficiently.
