Q fever is a zoonotic disease that is caused by the rickettsial organism *Coxiella burnetii* (1, 2) and has influenza-like symptoms, such as fever, chills, myalgia, headache, pneumonia, and bronchopneumonia. Although human Q fever was not recognized in Japan before the agent was isolated from patients, the disease is present in many countries (4). Oda and Yoshiie (6) reported that *C. burnetii* had been isolated from raw milk and uterus swab samples originating from dairy cattle with reproductive disorders, aborted bovine fetus samples, mammary gland samples originating from healthy dairy cattle, and tick samples originating from pastures. Furthermore, Nagaoka et al. (5) isolated *Coxiella* strains from children that had Q fever and influenza-like symptoms. These isolates were identified based on electron microscopic observations, protein and lipopolysaccharide profiles on sodium dodecyl sulfate-polyacrylamide gel electrophoresis gels, PCR amplification data, and immunological reactivity with *C. bumetii*-specific antiserum (5, 8, 9), but were not analyzed genetically. The phylogenetic diversity of six species belonging to the family *Rickettsiaceae*, including *C. burnetii*, has been noted, and *C. burnetii* is a member of the γ subdivision and is specifically related to the genus *Legionella* (10). Stein et al. (7) showed that all of the *C. burnetii* strains which they studied are highly related (>99%) on the basis of their 16S rRNA sequences, although they had different geographic origins and phenotypic characteristics, and that the genus *Coxiella* contains only one species, *C. burnetii*.

In this study, we genetically analyzed Japanese isolates obtained from various sources and geographical areas for Q fever. The 16S rDNA genes of Japanese *Coxiella* isolates obtained from various sources and geographical areas were directly sequenced by dideoxynucleotide chain termination methods in which Taq DNA polymerase was used. The levels of sequence similarity among Japanese, European, and American isolates were more than 99%, and the Japanese isolates were identified as *Coxiella burnetii*. *C. burnetii* strains isolated worldwide, including Japan, were found to be very similar.

The 16S rRNA genes of Japanese *Coxiella* isolates obtained from various sources and geographical areas were directly sequenced by dideoxynucleotide chain termination methods in which *Taq* DNA polymerase was used. The levels of sequence similarity among Japanese, European, and American isolates were more than 99%, and the Japanese isolates were identified as *C. burnetii*. *C. burnetii* strains isolated worldwide, including Japan, were found to be very similar.

The numbers in the designations of the primers indicate the locations of the primers in the 16S rRNA sequence of isolate 607. The sequences were aligned by using Genetic-Mac Automatic Connection of Sequences software (Software Development Co., Tokyo, Japan) and Genetic-Mac Genetic Information Processing software.

All of the isolates tested produced a 1,451-bp amplicon with primers QR-F0 and QR-R0. The 16S rRNA sequence of isolate 607, which was obtained from a patient who had influenza-like symptoms, was also determined by using primers QR-F0 and QR-R0. The sequencing primers used were designed on the basis of the sequence determined, and the entire sequence of the amplicon was determined by repeating the primer walking procedure. The ten sequencing primers were also used to sequence three C. burnetii strains (Bangui VR730, Ohio, and GQ212) from Europe and North America and five isolates (1M, 27M, 50F, 58T, and 607) from Japan. The sequences obtained in this study were aligned with the 16S rRNA sequence of C. burnetii Q177 (accession no. M21291). All of the strains, including the Japanese isolates obtained from various sources and geographical areas, exhibited high levels of similarity (more than 99%) (Table 2). The levels of sequence similarity among the test strains and Japanese isolates ranged from 99.1 to 99.9%. Interestingly, we did not find strains (including the five Japanese isolates) that had identical 16S rRNA sequences. The base substitutions observed are shown in Table 3. We found 17 base substitution points in the sequences of the strains used in this study. The previously published 16S rRNA sequence of strain Q177 differed at several nucleotide positions from the sequences of strains Bangui VR730, Ohio, GQ212, 1M, 27M, 50F, 58T, and 607 determined in this study. Only 12 nucleotide differences were found in the latter eight sequences, whereas 17 different nucleotides were found when the strain Q177 sequence was included. This result may imply that strain Q177 is unique.

This study revealed that the levels of sequence similarity among Japanese isolates and European and American isolates are more than 99%, and the Japanese isolates were identified as C. burnetii. C. burnetii strains isolated worldwide, including Japan, were found to be very similar, as previously reported (3, 7), and the genus Coxiella contains only one species, C. burnetii.
