The taxonomic status of an actinomycete (MA140/96T) isolated from indoor building materials of a children’s day care centre was studied using the polyphasic approach. The cell morphology was atypical for an actinomycete, electron microscopy revealed a hairy surface, highly unusual for Gram-positive bacteria. The organisms grew at 10–37 °C, no growth was visible at 5 °C and 45 °C in 5 d. The cell wall contained the diamino acid meso-diaminopimelic acid and the sugars arabinose, galactose, mannose and ribose. The phospholipids phosphatidylethanolamine, phosphatidylinositol, phosphatidylglycerol and diphosphatidylglycerol were detected. The only menaquinone found was MK-9(H2). The fatty acid pattern was composed of palmitic acid (23.6%) palmitoleic acid (16.5%) and another hexadecenoic acid 16:1cis11 (14%), oleic acid (29.9%), stearic acid (2.9%) and the 10-methyl-branched tuberculostearic acid (23.2%). A gas-chromatographic analysis of the mycolic acid revealed a carbon-chain length of C50–C56. The G+C was 64.8 mol%. The results of 16S rDNA sequence comparisons revealed that strain MA140/96T represents a new lineage in the suborder Corynebacterineae of the order Actinomycetales. Therefore, it was concluded that strain MA140/96T should be assigned to a new genus and species, for which the name Williamsia muralis gen. nov., sp. nov. is proposed. The type strain of the species is MA140/96T (= DSM 44343T).

Keywords: Williamsia muralis gen. nov., sp. nov., actinomycete, indoor contaminant

INTRODUCTION

The colonization of indoor building materials with bacteria and fungi is a common problem in case of high moisture (Maroni et al., 1995). In an extensive study of the bacteria, moulds and their toxins found in water-damaged buildings, Mycobacterium species and Gordonia species were detected (Andersson et al., 1997). Rapidly growing mycobacteria, especially, seem to be the major bacterial colonizers of water-damaged sites; however, it can be expected that several other actinomycetes are present, which remain to be described.

In a survey of a children’s day care centre, no mycobacteria or gordoniae were found in non-damaged areas; instead, a different type of actinomycete was detected. One isolate from these samples was subjected to an extensive polyphasic characterization. In this paper we describe the morphological, physiological, chemotaxonomic and phylogenetic characteristics of this organism. On the basis of our results and the unique taxonomic properties of the organism, it can be concluded that strain MA140/96T represents a new genus and a new species, for which we propose the name Williamsia muralis gen. nov., sp. nov.

METHODS

Isolation. The organism (strain MA140/96T) was isolated from non-water-damaged building material of a children’s day care centre as described elsewhere (Andersson et al., 1997). The strain was isolated from gypsum liner walls of a children’s sleeping room at 22 °C on tryptone soy agar plates (Difco) incubated for 14 d.

Morphological characteristics. Cell morphology was examined by phase-contrast microscopy with a light microscope (Leitz). Motility was studied by the hanging drop
method. Cell dimensions were measured with an ocular \((\times 10)\) and an objective \((\times 100/1.25)\). Gram staining was performed by using Hucker's modification (Gerhardt et al., 1994). Colony morphology was studied by using a stereo microscope (Olympus model SZ 11). For electron microscopy the cells were grown on tryptone soy agar for 7 d at 28 \(^\circ\text{C}\). Thin sections were prepared as described previously (Andersson et al., 1995) and negative stainings as described by Nohynek et al. (1995).

**Physiological characteristics.** The effects of different temperatures on growth were determined on Bacto nutrient agar incubated at 5, 10, 28, 37, 45 and 50 \(^\circ\text{C}\). Physiological tests in microtitre plates were done as described previously (Kämpfer et al., 1997). Tests were read after 7 d at 30 \(^\circ\text{C}\).

**Chemotaxonomy.** Strain MA140/96\(^T\) was grown on solidified glucose/yeast extract/malt extract DSMZ (Deutsche Sammlung von Mikroorganismen und Zellkulturen) medium no. 65 (DSMZ Catalogue of Strains, 1998) at 28 \(^\circ\text{C}\) for 3–5 d. Cell material for analyses of fatty acids and mycolic acids were scraped from trypticase soy broth agar plates (DSMZ medium no. 535). For all other chemotaxonomic analyses the strains were grown in trypticase soy broth collected by centrifugation washed twice with distilled water and freeze-dried.

**Analysis of cell-wall amino acids and sugars.** The amino acid and sugar analysis of whole-cell hydrolysate followed described procedures (Staneck & Roberts, 1974).

**Determination of acyl-type of cell wall.** The acyl-type of cell wall was determined using a modification of the colorimetric method of Uchida & Aida (1977). In contrast to the original procedures, the whole-cell hydrolysate was neutralized by passing it through an ion-exchange column (Analytichem Bond Elut SCX; Varian).

**Extraction and analysis of isopenoid quinones and polar lipids.** Isopenoid quinones were extracted and purified using the small-scale integrated procedure of Minnikin et al. (1984). Dried preparations were dissolved in 200 \(\mu l\) 2-propanol and 1–10 \(\mu l\) amounts separated by HPLC without further purification. The menaquinones were separated by HPLC on Lichrosorb RP-18 at 40 \(^\circ\text{C}\) using acetonitrile/2-propanol (65:35, v/v) as solvent (Kroppenstedt, 1985; Kroppenstedt et al., 1981). Polar lipids were extracted, examined by two-dimensional TLC and identified using published procedures (Minnikin et al., 1984).

**Preparation and analysis of fatty and mycolic acids.** The fatty acid methyl esters (FAMEs) and mycolic acid methyl esters (MAMEs) were prepared from 40–80 \(\mu g\) wet cells (Miller & Berger, 1984). The extracts of the methanolysates were split. One half (0.3 ml) of the extracts were used for the gas-chromatographic analysis of the FAMEs, and the other half was used for analysis of the MAMEs. For the analyses of the MAMEs by high-temperature gas chromatography, the hydroxy group of the MAMEs had to be converted to their trimethylsilyl ethers by a silylation reagent. The trimethylsilylated derivatives of the mycolic acids were prepared by mixing the extract with 0.1 ml of a solution containing \(\text{CHCl}_3\)-trimethylsilylchlorotrimethylsilane (10:1, v/v; Macherey & Nagel, Düren, Germany).

The mixtures of FAMEs and silylated derivatives of the MAMEs were analysed by capillary gas chromatography, using a Hewlett Packard model 5898A gas chromatograph run with Microbial Identification Software (MIDI). For FAME analysis, standard Microbial Identification System (MIS) conditions were used (Sasser, 1990). The trimethylsilylated derivatives of the MAMEs were analysed by high-temperature gas chromatography with a model HP 5790A gas chromatograph (Hewlett Packard) equipped with a flame-ionization detector and a 12 m type HT5 column (part no. 051385; SGE, Victoria, Australia), using \(\text{H}_2\) as carrier gas at a flow rate of 30 ml min\(^{-1}\). The oven temperature was increased from 210 to 400 \(^\circ\text{C}\) at a rate of 10 \(^\circ\text{C}\) min\(^{-1}\). The final temperature was kept for 7 min. Peaks of the derivatives were identified by comparing their retention times with those of known standard mycolic acids (Klatte, 1994). In addition the mycolic acids were analysed by TLC following the procedure of Minnikin et al. (1975).

**Base composition of DNA.** The base composition of DNA and the calculation of the G+C content was determined as described elsewhere (Nohynek et al., 1995).

**16S rRNA sequence determination.** Genomic DNA extraction, PCR-mediated amplification of the 16S rDNA, and purification of PCR products were carried out using procedures described previously (Rainey et al., 1996). Purified PCR products were sequenced using \(\text{Mg}^2\text{+DyeDeoxy Terminator Cycle Sequencing Kit (Applied Biosystems)}\) as directed in the manufacturer's protocol. The Applied Biosystems 310 DNA Genetic Analyzer was used for the electrophoresis of the sequence reaction products.

**Phylogenetic analysis.** The ae2 editor (Maidak et al., 1994) was used to align the 16S rDNA sequence of strain MA140/96\(^T\) against the 16S rDNA sequences of representatives of the suborder Corynebacterineae (Stückebrandt et al., 1997) available from the public databases. Pairwise evolutionary distances were computed using the correction of Jukes & Cantor (1969). The least squares method of De Soete (1983) was used in the construction of the phylogenetic dendrogram from distance matrices.

**Nucleotide sequence accession numbers.** The strain designations and accession numbers of the reference strains used in the phylogenetic analyses are as follows: *Corynebacterium glutamicum* DSM 20300\(^T\), X80629; *Deinococcus radiodurans* DSM 43672\(^T\), X79290; *Gordonia aichleinii* DSM 43978\(^T\), X80633; *Gordonia amarae* DSM 43392\(^T\), X80635; *Gordonia bronchialis* DSM 43247\(^T\), X79287; *Gordonia hirsuta* DSM 44140\(^T\), X93485; *Gordonia hydrophobica* DSM 44015\(^T\), X87340; *Gordonia rubropertincta* DSM 43197\(^T\), X80632; *Gordonia sputi* DSM 43896\(^T\), X80634; *Gordonia terrae* DSM 43249\(^T\), X79286; *Mycobacterium tuberculosis* H37Rv\(^T\), X55588; *Nocardia asteroides* DSM 43757\(^T\), X80606; *Nocardia brasiliensis* DSM 43758\(^T\), X80608; *Nocardia transvalensis* DSM 43405\(^T\), X80609; *Rhodococcus equi* DSM 20307\(^T\), X80614; *Rhodococcus erythropolis* DSM 43066\(^T\), X79289; *Rhodococcus globerulus* DSM 43954\(^T\), X80619; *Rhodococcus opacus* DSM 43205\(^T\), X80630; *Rhodococcus rhodochrous* DSM 43336\(^T\), X80621; *Rhodococcus rhodochrous* DSM 43241\(^T\), X79288; *Skanmerella piniformis* IFO 15059\(^T\), Z35435; *Tsukamurella paurometabola* DSM 20162\(^T\), X80628; *Tsukamurella pulmonis* IMMIB-D-1321\(^T\), X92981; *Turicella ottoides* DSM 8821\(^T\), X73976.

**RESULTS AND DISCUSSION**

**Phylogenetic position of strain MA140/96\(^T\)**

The almost complete 16S rDNA sequence of strain MA140/96\(^T\) comprising 1465 nucleotides \(\{>95\text{% of the Escherichia coli sequence}\}\) (Brosius et al., 1978) was

---

determined in this study. The phylogenetic dendrogram shown in Fig. 1 was reconstructed from evolutionary distances (Jukes & Cantor, 1969) by the least-squares distance method (De Soete, 1983). A total of 1386 nucleotides present in all strains between positions 38 and 1482 (*E. coli* positions) were used for this analysis and compared with the sequences representative of the phylogenetically defined suborder *Corynebacterineae*. The 16S rDNA sequence based phylogenetic tree shown in Fig. 1 indicates the position of strain MA140/96T within the radiation of representative taxa of the suborder *Corynebacterineae*. The 16S rDNA sequence of strain MA140/96T contains all of the 16S rDNA signature nucleotides defined for the suborder *Corynebacterineae* (Stackebrandt et al., 1997). 16S rDNA sequence similarity values between the that of strain MA140/96T and the taxa in the tree (Fig. 1) indicate that strain MA140/96T is not closely related at the 16S rDNA level to any previously described taxa. The sequence similarity values of the sequence of strain MA140/96T to other taxa are as follows: *Gordonia* species 94.2–95.6%, *Rhodococcus* species 94.0–95.7%, *Nocardia* species 94.0–95.7%, *S. piniformis* 94.0%, *Tsukamurella* species 93.9–94.1%, *D. maris* 92.4% and 88.8–91.8% to the outgroup organisms in the tree. These values and the tree (Fig. 1) show that strain MA140/96T is no more related and in some cases less related to any of the genera of the mycolic acid containing bacteria than those genera are to each other. Its lack of membership to one of the previously described genera based on the uniqueness of the 16S rDNA sequence of strain MA140/96T is seen when the signature nucleotides defined for the families of the suborder *Corynebacterineae* are searched in the sequence determined in this study. An example of this is that of the 11 signatures defined for the family *Gordoniacaeae* (Stackebrandt et al., 1997), all but one are absent in the 16S rDNA sequence of strain MA140/96T.

The distinctness of the 16S rDNA sequence and the isolated phylogenetic position of MA140/96T indicates that this isolate could merit genus status.

**Chemotaxonomy**

The hydrolysates of whole-cell cells of the strains contained the diamino acid *meso*-diaminopimelic acid and the sugars arabinose, galactose, mannose and ribose. This combination of the cell-wall diamino acid and sugar revealed the chemotype IV _sensu_ Lechevalier & Lechevalier (1970).
Whole-cell hydrolysates of all organisms contain meso-diaminopimelic acid and arabinose + galactose. Other diagnostic sugars like madurose, i.e. 3-O-methyl-D-galactose (Lechevalier & Gerber, 1970), xylose or rhamnose are lacking. Non-diagnostic sugars, i.e. glucose, mannose, ribose may be present (Lechevalier & Lechevalier, 1970). ND, Not determined.

* G, Glycated muramic acid; A, acetylated muramic acid.
† Phosphatidylethanolamine (Lechevalier et al., 1977, 1981); +, present; -, absent.
‡ S, Saturated fatty acids; U, unsaturated fatty acids; T, tuberculostearic acid.
§ Number of carbon atoms in mycolic acid molecule, range of homologous series of mycolic acids.
|| Fatty acid methyl esters released by pyrolysis of mycolic acid methyl esters.

** Tuberculostearic acid present in C. ammoniagenes, C. bovis, C. minutissimum, C. urealyticum and C. variabilis.
†† Abbreviation MK-9 = 2-methyl-3-nonaisoprenyl-1,4-naphthoquinone (Collins & Jones, 1981; Kroppenstedt, 1985; Goodfellow, 1989).

The following phospholipids were detected: phosphatidylethanolamine, phosphatidylglycerol, phosphatidylglycerol and diphosphatidylglycerol. According to the phospholipid classification of Lechevalier et al. (1977) the strains showed phospholipid type II [containing phosphatidylethanolamine but lacking phosphatidylcholine and glucosamine-containing phospholipid (Glu-Nu)]. The only menaquinone found was MK-9(H2).

The fatty acid pattern was mainly composed of palmitic acid (23.6%), palmitoleic acid (16.5%) and another hexadecenoic acid 16:1ω11 (1.4%), oleic acid (29.9%), stearic acid (2.9%) and the 10-methyl-branched tuberculostearic acid (23.1%). Small amounts of 17:0 (1.4%) and 17:1 (1.3%) could be found in addition. iso- and anteiso-branched and cyclopropane fatty acids were absent. This fatty acid pattern corresponds to fatty acid type 1b of Kroppenstedt (1985). The gas-chromatographic analyses of the mycolic acid revealed a carbon-chain length of C_{50}-C_{66} and a quantitative distribution of C_{50} 10%, C_{52} 5%, C_{54} 34%, C_{55} 5%, C_{56} 36%, C_{57} 6% and C_{66} 6%. On a thin-layer plate a single spot was detected showing an R_f-value of 0.35 which resembles mycolic acids which are synthesized by Rhodococcus, Nocardia and Gordonia (Minnikin et al., 1975).

A detailed comparison of chemotaxonomic data of MA140/96T with other mycolic acid-containing genera is given in Table 1. Although almost all chemotaxonomic markers of MA140/96T resemble those of Gordonia, members of these two genera can easily be differentiated by the chain length of their mycolic acids. MA140/96T synthesized a homologous series of mycolic acids of a chain length of 50–56 carbon atoms whereas those of Gordonia spp. are longer. Based on the mycolic acids it seems that MA140/96T takes an intermediate position between Rhodococcus (mycolic acid chain length of 34–54) and Gordonia (mycolic acid chain length of 54–66). Also, MA140/96T contained more tuberculostearic acid (>20%) than any of the Gordonia species described so far.

** Morphological characteristics

Strain MA140/96T grew as round, slightly convex, colonies that were 1–3 mm in diameter and were mainly pale yellow to intense yellow. The cells were Gram-positive, non-acid-fast, non-motile, thin irreg...
Williamsia muralis gen. nov., sp. nov.

Fig. 2. Phase-contrast photomicrograph of strain MA140/96T grown on tuberculostearic acid agar for 48 h (bar, 5 μm).

ular rods or coccoid (0.5–0.8 μm × 1.0–2.0 μm) that occurred singly, or in small clusters (Fig. 2). Some longer cells (5 μm) were also observed (Fig. 2), but like many other members of the suborder Corynebacterineae the cell morphology was amycelial. Endospores were not observed. Transmission electron micrographs (Fig. 3a) revealed the presence of hairy structures distributed over the whole surface of each cell. With the exception of the genus Bogoriella (Groth et al., 1997) and the species Rhodococcus percolatus (Briglia et al., 1996), such structures have not been found previously in coryneform organisms. However, the appendages of the strain MA140/96T were not visible in negative-stained preparations (Fig. 3b), which indicates that they may be fibrillar capsular material rather than true fimbriae.

Cultural characteristics

Strain MA140/96T was isolated on tryptone soy agar (Difco) at 22 °C, but also grow on Bacto nutrient agar in a temperature range from 10 to 37 °C. Growth at low and high temperatures was delayed and reduced, especially at 37 °C. At 45 °C only traces of growth were observed.

Physiological characteristics

The physiological properties of strain MA140/96T can be summarized as follows: Utilization of the following carbon sources was observed after 4 d incubation at 30 °C: acetate, adonitol, citrate, D-fructose, fumarate, D-gluconate, D-mannitol, D-mannose, propionate, putrescine, L-rhamnose, sorbitol, sucrose and pyruvate. After prolonged incubation (10 d) growth with D-glucose, DL-3-hydroxybutyrate, L-alanine and L-proline was observed in addition. The following carbon sources could not be used for growth: N-acetyl-D-galactosamine, N-acetyl-D-glucosamine, cis-aconitate, trans-aconitate, β-alanine, 4-amino-butyrate, L-arabinose, p-arbutin, L-aspartate, azelate, p-cellobiose, glutarate, L-histidine, 3-hydroxybenzoate, 4-hydroxybenzoate, inositol, itaconate, DL-lactate, L-leucine, L-malate, D-maltitol, D-maltose, α-D-melibiose, mesaconate, 2-oxoglutarate, L-ornithine, phenylacetate, L-phenylalanine, salicin, L-serine, suberate, D-trehalose, L-tryptophan or D-xylose. The following chromogenic substrates were hydrolysed after 4 d incubation (pNP = para-nitrophenyl; pNA = para-nitroanilide): pNP-α-D-glucopyranoside, bis-pNP-phosphate. No hydrolysis of aesculin, pNP-β-D-

16S rDNA analysis clearly indicated that this organism is not a member of the genus *Gordonia*, because the signature nucleotides of the family *Gordoniaceae* are not present. Although the chemotaxonomic properties are similar to that of the species of the genus *Gordonia*, it can be easily differentiated by the chain length of their mycolic acids. In addition, the high amount of tuberculostearic acid (＞20%) can be used for separation from the species *Gordonia*. A combination of genotypic and phenotypic data clearly show that strain MA140/96T merits recognition as a new genus within the suborder *Corynebacterineae*.

**Williamsia** (Wil.li.ams.ia. M.L. fem. n. named to honour Stanley T. Williams, a British microbiologist, for his numerous contributions to the taxonomy and ecology of actinomycetes).

Gram-positive, non-spore forming short rods. A hairy surface distributed over the whole surface of each cell is visible by transmission electron microscopy, but not in negative-stained preparations. Aerobic and chemo-heterotrophic. The diagnostic amino acid is *meso*-diaminopimelic acid and the major cell-wall sugars are arabinose, galactose, mannose and ribose (wall chemo-type IV sensu Lechevalier & Lechevalier, 1970). Short-chain mycolic acids are present (carbon-chain length of C50-C56). The fatty acid pattern is mainly composed of straight-chain saturated and monounsaturated fatty acids. Tuberculostearic acid is present in large amounts (＞20% of the whole-cell fatty acid). The major polar lipids are phosphatidylethanolamine, phosphatidylinositol, phosphatidyglycerol and diphosphatidylglycerol. Menaquinone MK-9(H2) is the only isoprenologue. On the basis of 16S DNA sequence analysis it is a member of the suborder *Corynebacterineae*. The G+C content of the DNA is 64-65 mol%.

**Description of Williamsia muralis** sp. nov.

*Williamsia muralis* [mu.ral.is. L. adj. muralis, -le pertaining or belonging to wall(s)]. Coccoid cells without branching (0-4-0.5 μm in width, 0.6-1.4 μm in length). Smooth, saffron yellow colour on TSB agar (BBL). The temperature range for growth is 10 to 37 °C, optimum at 30 °C. No growth could be detected at 4 or 41 °C. Good growth was observed on nutrient agar (Difco), R2A agar (Difco) and TSB agar (BBL). Acetate, adonitol, citrate, D-fructose, fumarate, D-glucuronate, D-mannitol, d-mannose, propionate, pyruvate, pu-trescine, L-rhamnose, sorbitol, succrose and pyruvate are utilized (after 4 d incubation at 30 °C) as sole source of carbon. In addition, D-glucose, DL-3-hydroxybutyrate, L-alanine and L-proline are utilized after 10 d incubation. pNP-α-D-glucopyranoside and bis-pNP-phosphate are hydrolysed. The G+C content of the DNA is 64-8 mol%. Isolated from indoor building material of a children’s day care centre, Finland. MA140/96T is the type strain of the species and has been deposited at the German Collection of Microorganisms and Cell Cultures as strain DSMZ 44343T.

**ACKNOWLEDGEMENTS**

We thank Gabriele Pötter-Reinemann, F. Frerichs and Verena Schmidt for technical assistance, M.S.-S. thanks the Academy of Finland and Helsinki University Fund for Centers of Excellence for financial support (grant no. 34519). Irina Tsistko and Raimo Mikkola are thanked for analytical help. Helsinki University EM-unit (Biocenter) is thanked for the use of their equipment.
