Lactic acid bacteria (LAB), especially the genera \textit{Lactococcus}, \textit{Lactobacillus} and \textit{Leuconostoc}, are the most important group of micro-organisms involved in food fermentation (Hammes & Tichaczek, 1994; Herrero \textit{et al}., 1996). The microbial ecology of sourdough fermentation is determined by various exogenous and endogenous parameters (Vogel \textit{et al}., 1999). The sourdough microflora comprises LAB and yeasts existing in symbiotic relationships (Hammes & Gänzle, 1998). Yeasts contribute predominantly to dough leavening, whereas LAB are responsible for acidification, aroma formation and sensorial as well as nutritional improvement of the fermented product (Böcker \textit{et al}., 1990; Hammes \textit{et al}., 1996).

France, as with many other countries, has a long tradition in bread making. Reports concerning the LAB biodiversity observed in natural French sourdough revealed a broad spectrum of different LAB, predominant among which are members of the genus \textit{Lactobacillus}, e.g. \textit{Lactobacillus plantarum}, \textit{Lactobacillus brevis} and \textit{Lactobacillus sanfranciscensis} (Bervas, 1991; Infantes, 1992; Onno & Roussel, 1994; Gabriel \textit{et al}., 1999). For the development of stable starter cultures, a thorough analysis of the typical sourdough microflora is indispensable. In this study, the biodiversity of LAB in three fermented wheat sourdoughs from different regions of France was investigated. A preliminary screening performed. These analyses allowed the identification of \textit{Lactobacillus} strains were not assignable to any recognized species. Consequently, we describe and classify these strains as representing a novel \textit{Lactobacillus} species, for which we propose the name \textit{Lactobacillus hammesii} sp. nov.

The bacterial diversity of three French wheat sourdoughs was investigated at the LMAI – ENITIAA (Nantes, France). These were firm sourdoughs maintained by back slopping or \textit{rafraichi} in different specific conditions for each sourdough in terms of ratio (sourdough/dough), temperature

Twenty morphologically different strains were chosen from French wheat sourdough isolates. Cells were Gram-positive, non-spore-forming, non-motile rods. The isolates were identified using amplified-fragment length polymorphism, randomly amplified polymorphic DNA and 16S rRNA gene sequence analysis. All isolates were members of the genus \textit{Lactobacillus}. They were identified as representing \textit{Lactobacillus plantarum}, \textit{Lactobacillus paralimentarius}, \textit{Lactobacillus sanfranciscensis}, \textit{Lactobacillus spicheri} and \textit{Lactobacillus sakei}. However, two isolates (LP38\(^T\) and LP39) could be clearly discriminated from recognized \textit{Lactobacillus} species on the basis of genotyping methods. 16S rRNA gene sequence similarity and DNA–DNA relatedness data indicate that the two strains belong to a novel \textit{Lactobacillus} species, for which the name \textit{Lactobacillus hammesii} is proposed. The type strain is LP38\(^T\) (= DSM 16381\(^T\) = CIP 108387\(^T\) = TMW 1.1236\(^T\)).
(18–26 °C) and back slopping frequency. Twenty colonies were isolated on modified MRS agar (De Man et al., 1960) supplemented with 1 % (w/v) maltose and 0.5 % (w/v) fresh yeast extract prepared according to the method of Kline & Sugihara (1971). LAB were grown anaerobically at 30 °C for 48 h. The distribution of various colony forms was recorded and distribution percentages of the various isolates were determined. Pure culture was obtained by successive subculturing on identical medium. For biochemical characterizations mMRS4 medium was used (Stolz et al., 1996). Lactobacillus reference strains were obtained from the DSMZ or from the TMW culture collection at Lehrstuhl für Technische Mikrobiologie (Freising, Germany).

DNA was isolated according to the method of Marmur (1961) with the modifications described by Ehrmann et al. (2003). The isolated DNA was used for AFLP, RAPD and 16S rRNA gene sequence amplification. RAPD-PCR was carried out as described by Ehrmann et al. (2003) and AFLP analysis was performed according to Schmidt et al. (2003). Data analysis was performed using the BIONUMERICS software (Applied Maths). This program recorded the normalized electrophoretic patterns of the densitometric traces, grouped the isolates by the Pearson product–moment correlation coefficient and performed UPGMA cluster analysis of the bands. The complete 16S rRNA gene was amplified using primers 616V and 630R according to Mesbah et al. (1989). All experiments were carried out in duplicate by DSMZ staff.

gram staining, cell morphology and catalase activity were examined after 24 h of incubation on MRS agar. Sugar fermentation patterns were determined using the API 50CH kit (bioMérieux) over a period of 72 h. D/L-Lactate production was measured using an enzymic kit from Microzym (Diffchamb). To determine the temperature and pH growth optima as well as salt tolerance, cultures were grown on mMRS4 medium, harvested, washed with fresh medium, inoculated (1 %) and incubated at various temperatures (15, 20, 25, 30, 35, 40 and 45 °C) and pH values (3, 4, 4.5, 5, 5.5, 6, 6.7 and 8). Bacterial growth was monitored by measurement of the optical density at 590 nm. Production of ammonia from arginine was determined according to the method of Abo-Elnaga & Kandler (1965). Mannitol formation from fructose was demonstrated by HPLC as described by Müller et al. (2001). All tests for biochemical characterizations were carried out at least in duplicate.

The LAB microfloras of three wheat sourdoughs prepared by back slopping propagation from previous batches were characterized. The total LAB count in the studied sourdoughs ranged from 1·6 × 10⁸ to 2·1 × 10⁹ c.f.u. g⁻¹ and the final sourdough pH was between 4·0 and 4·2. Twenty morphologically different colonies were isolated from each sourdough and these were phenotypically characterized. All cells were Gram-positive, catalase-negative, facultatively anaerobic rods. The isolates were identified using AFLP, RAPD and 16S rRNA gene sequence analysis. All were members of the genus Lactobacillus. They were identified as Lactobacillus plantarum, Lactobacillus paralimentarius, Lactobacillus sanfranciscensis, Lactobacillus spichieri and Lactobacillus sakei. However, two isolates, LP38 and LP39, were clearly discriminated from recognized Lactobacillus species. The complete sequences (1559 bp) of the 16S rRNA genes of these two strains were determined. The two sequences showed high similarity (99·7%), suggesting that the strains belong to the same species. In a neighbour-joining dendrogram (Fig. 1) based

![Fig. 1](image-url)
on 16S rRNA gene sequences obtained from this study and from the GenBank database, strains LP38<sup>T</sup> and LP39 clearly belong to the genus *Lactobacillus*, and are positioned close to *Lactobacillus brevis*, *Lactobacillus spicheri*, *Lactobacillus zymae* and *Lactobacillus acidifaciariae*, all of which have been isolated from sourdoughs (Vancanneyt et al., 2005).

DNA–DNA reassociation analyses were performed including the three most closely related strains based on 16S rRNA gene sequence analysis. DNA–DNA relatedness values of LP38<sup>T</sup> to *Lactobacillus spicheri*, *Lactobacillus zymae* and *Lactobacillus brevis* were 64·7 ± 2·5, 43·3 ± 4·3 and 18·3 ± 8·1 %, respectively. These values are below the threshold of 70 % suggested for species delineation (Stackebrandt & Goebel, 1994), indicating that strain LP38<sup>T</sup> represents a separate genomic species. The DNA G+C content of LP38<sup>T</sup> is 52·6 mol%, which is within the range (32–55 mol%) reported for *Lactobacillus* (Kandler & Weiss, 1986). Analysis of the cell wall composition of strain LP38<sup>T</sup> revealed the presence of lysine and aspartic acid, indicating an A4<sub>2</sub> L-Lys–D-Asp peptidoglycan type. Strain LP38<sup>T</sup> accounted for about 30 % (5 × 10<sup>8</sup> to 6 × 10<sup>8</sup> c.f.u.) of the total LAB in investigated sourdoughs, and the rest were strains of the species *Lactobacillus plantarum*, *Lactobacillus sanfranciscensis*, *Lactobacillus paralimentarius*, *Lactobacillus spicheri* and *Lactobacillus sakei*. Physiological properties and sugar fermentation patterns of strains LP38<sup>T</sup> and LP39 are shown in Table 1.

Müller et al. (2001) reported the application of RAPD-PCR for the analysis of the microflora of an industrial sourdough. When the RAPD patterns of the 20 isolates were compared to those of reference lactobacilli usually found in sourdough, strain LP38<sup>T</sup> showed no similarity to any other isolates or reference *Lactobacillus* strains (see Supplementary Fig. A in IJSEM Online), which confirmed the 16S rRNA gene sequence analysis results. Torriani et al. (2001) reported discrimination between the closely related species *Lactobacillus plantarum*, *Lactobacillus paraplantarum* and *Lactobacillus pentosus* using RAPD-PCR and AFLP. Analogously to RAPD analysis, AFLP patterns of the sourdough isolates were compared with those of reference *Lactobacillus* strains. AFLP grouped the 20 sourdough isolates into five groups identical to those obtained by RAPD (Supplementary Fig. B).

The microflora of the investigated sourdoughs showed the typical composition frequently reported in French and Italian sourdoughs, *Lactobacillus plantarum*, *Lactobacillus sanfranciscensis*, *Lactobacillus paralimentarius* and *Lactobacillus sakei* (Bervas, 1991; Infantes, 1992; Onno & Roussel, 1994; Hammes et al., 1996; Gobetti et al., 1994). However, isolation and identification of nine isolates as *Lactobacillus spicheri*, which has been isolated as a novel species from rice sourdough (Meroth et al., 2004), represents the first isolation of this species from a wheat sourdough. Strain LP38<sup>T</sup> exhibited no similarity to any other sourdough isolates or *Lactobacillus* reference strains using RAPD or

AFLP, and analysis of the complete 16S rRNA gene sequence revealed that the bacterium is closely related to Lactobacillus brevis and Lactobacillus spicheri. On the basis of these results we propose that strains LP38T and LP39 be classified in the genus Lactobacillus as Lactobacillus hammessi sp. nov.

Description of Lactobacillus hammessi sp. nov.

Lactobacillus hammessi (ham.me.si’i. N.L. gen. n. hammessi of Hammes, in honour of Walter P. Hammes, a German scientist who contributed to the microbiological and technological development of wheat and rye sourdough research).

Cells are Gram-positive, catalase-negative, non-motile, non-spore-forming straight rods that occur singly (0.5 × 2–4 μm), in pairs or occasionally in short chains. Colonies on MRS agar appear white and circular with a smooth surface and edges (1–1.5 mm in diameter after 2 days of growth). Cells grow well in liquid or solid MRS under aerobic conditions. Strain LP38T grows at 15°C but not at 45°C. Optimum temperature for growth is 30–35°C and the optimal initial pH is 4.7–7.2. Specific growth rate of strain LP38T in mMRS4 at pH 6.2 and at 30°C is 0.42 ± 0.01 h⁻¹. Strain LP38T is able to grow well at up to 2% NaCl; at 6.6% NaCl the specific growth rate is 26% (100% without NaCl). Glucose is metabolized heterofermentatively. Glucose, maltose, arabinose, xylose, galactose, mannose, cellobiose and trehalose are fermented by strain LP38T. Ammonia is not produced from arginine. Fructose is used either as an energy source or as an electron acceptor and is reduced to mannitol. Both strains LP38T and LP39 produce lactate at a ratio of 45% L-lactate to 55% D-lactate. Strain LP38T grows significantly better in media containing electron acceptors such as fructose in addition to a carbon source (maltose or glucose). HPLC analysis revealed that strain LP38T produces lactic acid and ethanol from glucose or maltose and, in the presence of fructose, produces lactic and acetic acid. Peptidoglycan structure is A4α L-Lys–D-Asp type and the DNA G+C content is 52.6 mol%.

The type strain is LP38T (= DSM 16381T = CIP 108387T = TMW 1.12361T).

Acknowledgements

We are grateful to Florian Waldherr for biochemical characterization, Isabelle Hue for technical support and Carrie Hew for revision of the manuscript. Luc De Vyust, Vrije Universiteit Brussel, is acknowledged for providing 16S rRNA gene sequences of Lactobacillus zymae and Lactobacillus acidifarinae ahead of publication. This work was partially supported by the French Ministry (Ministère des Affaires Etrangères) and by the Federation of European Microbiological Societies (FEMS).
