2Graduate University of Chinese Academy of Sciences, Beijing 100049, People's Republic of China

Three Gram-negative, non-spore-forming strains were isolated from sediment from the South China Sea, China, and their taxonomic positions were investigated using a polyphasic approach. Strains HN-171T, HN-172 and HN-181 grew optimally at 30 °C, in the presence of 4.5–5.0 NaCl % (w/v) and at pH 7.2–7.4. They contained MK-6 as the predominant respiratory quinone and contained iso-C15:0, summed feature 4 (iso-C15:0 2-OH and/or C16:1ω7c), and C15:0 as the major fatty acids. The DNA G+C content of strain HN-171T was 34.5 mol%. Phylogenetic analyses based on 16S rRNA gene sequences demonstrated that strain HN-171T, together with strains HN-172 and HN-181, formed a distinct evolutionary lineage within the family *Flavobacteriaceae*. The 16S rRNA gene sequences of strains HN-171T, HN-172 and HN-181 shared 99.8–100 % similarity with each other, and the sequence of strain HN-171T exhibited similarity values below 90 % with those of other members of the family *Flavobacteriaceae*. The closest relative of HN-171T was *Coenonia anatina* LMG 14382T (90.2 %). On the basis of their phenotypic and phylogenetic properties, the three isolates represent a novel genus and a novel species, for which the name *Zhouia amylolytica* gen. nov., sp. nov. is proposed. The type strain is HN-171T (=CGMCC 1.6114T=JCM 14018T).

The family *Flavobacteriaceae* was proposed by Jooste (1985), and its description has since been subjected to repeated emendation (Bernardet et al., 1996, 2002). In addition to providing phylogenetic data, Bernardet et al. (2002) proposed minimal standards for separating the genera classified as belonging to the family *Flavobacteriaceae*: these standards included characteristics relating to pigmentation, gliding motility, the seawater requirement, growth at different temperatures, cellular fatty acid composition and DNA G+C content. Currently, the family *Flavobacteriaceae* contains 53 genera with validly published names. Twenty-two of these genera were established within the last 5 years, being based on bacterial isolates from marine environments: *Aequorivita*, *Alegibacter*, *Aquimarina*, *Arenibacter*, *Bizonia*, *Croceibacter*, *Dokdonia*, *Donghaeana*, *Gaetbulibacter*, *Gaetbulimicrobium*, *Gramella*, *Lacinutrix*, *Maribacter*, *Mesonia*, *Muricauda*, *Olleya*, *Robiginitalea*, *Stenothermobacter*, *Subsaxibacter*, *Subsaximicrobium*, *Ul Vibacter* and *Winogradskyella* (Bowman & Nichols, 2002, 2005; Bruns et al., 2001; Cho & Giovannoni, 2003, 2004; Ivanova et al., 2001; Jung et al., 2005; Lau et al., 2006; Mancuso et al., 2005; Nedashkovskaya et al., 2003, 2004a, c, d, 2005a, b, c, d; Yoon et al., 2005, 2006a, b). The abundance of marine members of the *Flavobacteriaceae* suggests that the family potentially plays an important role in marine ecosystems and in biogeochemical cycles, in interaction with other marine organisms.

During a survey of the ecology and bacterial diversity of the South China Sea, many bacterial strains were isolated. Three of them, designated HN-171T, HN-172 and HN-181, form a deep branch within the family *Flavobacteriaceae*. In this communication, we describe the isolation of these three bacterial strains and our study using polyphasic taxonomy.

A sediment sample was collected from the South China Sea, China (sample site GPS position, 115° 15′ 90″ E 21° 18′ 65″ N); the salinity of the overlying water was 3 %. Strains were isolated by spreading sample dilutions on marine agar 2216 (MA; Difco) and incubating the plates at 30 °C. The cell morphology was examined by transmission electron microscopy (H600; Hitachi) and scanning electron microscopy (200; FEI Quanta). Gliding motility and flexirubin pigments were investigated according to the methods...
specified in the minimal standards for describing new taxa of the family Flavobacteriaceae (Bernardet et al., 2002). The Gram reaction was determined using cells grown on MA at 30°C for 24 h, according to the method described by Gerhardt et al. (1994). Endospore formation was determined after malachite-green staining (Dong & Cai, 2001) of cells grown on MA. The pH range for growth was determined in marine broth 2216 (MB; Difco) that was adjusted to various pH values (pH 4–9), in increments of 0.5 pH units) with HCl or NaOH prior to sterilization.

Growth in the presence of various NaCl concentrations was investigated in MB: the final concentrations (i.e. including the original concentration in MB) are given below. Growth at various temperatures (4–45°C) in increments of 5°C was measured on MA. Anaerobic growth was determined in MB in an anaerobic test tube filled with nitrogen gas. Catalase activity was assessed from the formation of bubbles after a 3% H2O2 solution was dropped onto a fresh colony. Oxidase activity and the hydrolysis of casein, starch, gelatin and Tween 20, 40, 60 or 80 were determined as described by Dong & Cai (2001) with artificial seawater. The ability of the three isolates to utilize a battery of 95 different carbon sources was tested using GN MicroPlates (Biol) inoculated with cells suspended in sterile artificial seawater. The artificial seawater contained the following (l−1 distilled water): 23.6 g NaCl, 0.64 g KCl, 4.53 g MgCl2·6H2O, 5.94 g MgSO4·7H2O and 1.3 g CaCl2·2H2O (Bruns et al., 2001). Cells for the analysis of cellular fatty acids were grown on MA for 2 days at 30°C, and the cellular fatty acid composition was determined as described previously (Hu et al., 2004, and references therein). Biomass for the analysis of isoprenoid quinones was grown in MB; the quinones were determined according to Collins (1985) and Wu et al. (1989). DNA G+C contents were determined by thermal denaturation (Marmur & Doty, 1962) using the DNA of Escherichia coli DH5α as a standard for calibration of the Tm value. The 16S RNA gene was amplified and sequenced as described previously (Zhang et al., 2003) and sequences were aligned using the CLUSTAL X program (Thompson et al., 1997). Phylogenetic trees were constructed using the neighbour-joining method (Saitou & Nei, 1987) with the Kimura two-parameter model in TRECECON W, version 1.3b (Van de Peer & De Wachter, 1994) and the maximum-parsimony method (Fitch, 1971).

The morphological, physiological and biochemical characteristics of strain HN-171T are given in the species description. The differentiating features for the three isolates and phylogenetically related genera are listed in Table 1. The almost-complete 16S rRNA gene sequence (1478 nt) of strain HN-171T was determined. Phylogenetic trees based on 16S rRNA gene sequences showed that strains HN-171T, HN-172 and HN-182 form a distinct phylogenetic lineage within the family Flavobacteriaceae (Fig. 1); strain HN-171T exhibits the highest similarity to Coenonia anatina LMG 14382T (90.2%).

The isoprenoid quinone of strains HN-171T, HN-172 and HN-181 was MK-6. All three strains contained branched, hydroxyl, straight-chain and unsaturated fatty acids. The fatty acid profile of strain HN-171T (>1% of total fatty acids) comprised iso-C15:0 G (24.2%), iso-C15:0 (14.9%), summed feature 4 (iso-C15:0 2-OH and/or C16:1ω7c/ω6c) (10.7%), C15:0 (9.4%), C16:0 (4.9%), iso-C15:0 3-OH (3.9%), C14:0 (2.5%), C15:0 2-OH (1.4%), iso-C13:0 3-OH (1.4%) and anteiso-C15:0 (1.1%). The DNA G+C content of strain HN-171T was 34.5 mol% (Tm).

The three isolates differed from their close phylogenetic neighbours in the family Flavobacteriaceae in terms of a number of phenotypic and chemotaxonomic properties (Table 1). In particular, the novel isolates contained the characteristic fatty acid summed feature 4. On the basis of the phenotypic and phylogenetic data, we propose the creation of a novel genus and species in the family Flavobacteriaceae, Zhouia amylolytica gen. nov., sp. nov., to accommodate the three strains HN-171T, HN-172 and HN-181.

**Description of Zhouia gen. nov.**

*Zhouia* (Zhou’i.a. N.L. fem. n. Zhouia named after Professor Pei-Jin Zhou, a pioneer of environmental microbiology in China).

Cells are Gram-negative, non-motile, non-spore-forming rods. Strictly aerobic. NaCl is required for growth. Positive for oxidase and catalase. The menaquinone is MK-6. The

*Summed feature 4 contains iso-C15:0 2-OH and/or C16:1ω7t.

Major fatty acids are iso-C15:1, iso-C15:0 and summed feature 4. The type species is Zhouia amylolytica.

Description of Zhouia amylolytica sp. nov.

Zhouia amylolytica (a.my.lo.ly’ti.ca. Gr. n. amyllos starch; N.L. adj. lyticus from Gr. adj. luktos dissolving; N.L. fem. adj. amylolytica dissolving starch, pertaining to the ability of the bacterium to hydrolyse starch).

Exhibits the following properties in addition to those given in the genus description and in Table 1. Cells are 0·25-0·3×1·3-3·0 μm in size; devoid of flagellar and gliding motility. Colonies on MA are circular, slightly raised, smooth, yellow to pale-yellow in colour and 2·0-3·0 mm in diameter after incubation for 2 days at 30 °C. Growth occurs at 7-42 °C, with an optimum at 30 °C; growth does not occur at 4 or 45 °C. Growth is observed at pH 6·0-8·0, with an optimum at pH 7·2-7·4; growth does
not occur at pH 5.8 or 8.2. Optimal growth occurs in the presence of 4.5–5.5% (w/v) NaCl; growth does not occur in the absence of NaCl or in the presence of >9% (w/v) NaCl. Nitrate is not reduced. Starch and gelatin are hydrolysed, D-galactose, gentiobiose, 2-D-lactose, maltose, D-melibiose, methyl β-D-glucoside, D-psicose, D-raffinose, L-rhamnose, D-sorbitol, D-trehalose, turanose, succinic acid monomethyl ester, acetic acid, D-galactonolactone, α-ketobutyric acid, α-ketoglutaric acid, α-ketovaleric acid, DL-lactic acid, succinic acid, L-glutamic acid, glycyl L-aspartic acid, glycyl L-lysine, sucrose, α-D-glucoside, D-psicose, D-raffinose, L-rhamnose, L-sorbose, adonitol, L-arabinose, D-arabitol, i-erythritol, L-ascorbic acid, fucose, glucuronamide, L-alaninamide, L-alanine, L-arginine, L-asparagine, L-aspartic acid, L-glutamic acid, D-glutamic acid, D-glutamine, methionine, myo-inositol, L-proline, L-threonine, D-threonic acid, inosine, uridine, D-glucose 1-phosphate and D-glucose 6-phosphate are utilized. Tweens 40 and 80, DL-carnitine, thymidine, phenylethyl-alcohol, D-mannitol, xylitol, methyl pyruvate, adonitol, L-arabinose, D-arabitol, i-erythritol, myo-inositol, L-mannitol, xyitol, methyl pyruvate, cis-aconitic acid, citric acid, formic acid, D-galactonic acid, D-gluconic acid, D-glucosaminic acid, D-glucuronic acid, L-alanine, L-alanyl glycine, L-asparagine, L-aspartic acid, D-serine, L-serine, D-2-aminoethylglycine, L-asparagine, L-aspartic acid, L-histidine, L-phenylalanine, L-proline, D-serine, L-serine, D-threonic acid, α-aminobutyric acid, thymidine, phenylethylamine, putrescine, 2-aminoethanol, 2,3-butanediol, glycerol and DL-α-glycerol phosphate are not utilized. The major fatty acids are iso-C₁₅:₀ (14.9%), summed feature 4 (10.7%), and C₁₅:₀ (9.4%). The DNA G+C content of the type strain is 34.5 mol%.

The type strain, HN-171ᵀ (＝CGMCC 1.6114ᵀ＝JCM 14016ᵀ), was isolated from a sediment sample from the South China Sea, China.
