**Brevibacterium samyangense** sp. nov., an actinomycete isolated from a beach sediment

Soon Dong Lee

Department of Science Education, Cheju National University, Jeju 690-756, Republic of Korea

The genus *Brevibacterium*, originally proposed by Breed (1953), is clearly differentiated from actinomycete genera with coryneform morphology on the basis of chemotaxonomic characteristics (Collins et al., 1983) and 16S rRNA gene sequence analysis (Heyrman et al., 2004; Wauters et al., 2004).

The genus contained, at the time of writing, 15 recognized species, mainly recovered from dairy products, clinical specimens, poultry and terrestrial environments, although a few, including *Brevibacterium celere* (Ivanova et al., 2004) and *Brevibacterium stationis* (Jones & Keddie, 1986), were recovered from samples collected in marine environments. In the 16S rRNA gene sequence studies performed by Heyrman et al. (2004), *B. stationis* was shown to be related to members of the genus *Corynebacterium*. In the present study, a novel member of the genus *Brevibacterium*, recovered from beach sediment, was characterized taxonomically by use of a polyphasic approach. The resultant data supported that the organism should be classified as a novel species of the genus *Brevibacterium*.

During a study of marine actinomycetes, strain SST-8\(^T\) was isolated from beach sediment of the coast of Jeju Island, Republic of Korea, and its taxonomic status was investigated. A sediment sample was taken at a depth of 30 cm below the beach surface. For bacterial isolation, 1 g sediment was placed into a sterile plastic tube containing 9 ml sterile distilled water and mixed in a tube rotator for 30 min. After aliquots (100 \(\mu\)l) of the sample were transferred into the isolation medium, the agar plates were incubated at 30 °C for 14 days. The isolation medium (SC-SW agar) consisted of 1 % soluble starch, 0-03 % casein, 0-2 % \(\text{KNO}_3\), 0-2 % \(\text{NaCl}\), 0-002 % \(\text{CaCO}_3\), 0-005 % \(\text{MgSO}_4\cdot7\text{H}_2\text{O}\), 0-001 % \(\text{FeSO}_4\cdot7\text{H}_2\text{O}\), 1-8 % agar, 60 % natural seawater and 40 % distilled water (pH 7-2). Colonies were subcultivated on ISP2 medium (Shirling & Gottlieb, 1966) supplemented with 60 % (v/v) sterilized natural seawater (YE-SW agar). Pure cultures were maintained on YE-SW agar plates and in 20 % (v/v) glycerol solution supplemented with 60 % (v/v) sterilized natural seawater at -20 and -80 °C.

Analysis of cellular fatty acids was performed according to the instructions of the Microbial Identification System (MIDI) (Sherlock Microbial Identification System; Hewlett Packard), with cells grown on tryptase soy agar for 48 h. Other chemotaxonomic characters were analysed as described by Lee et al. (2000b) as follows: the isomer of diaminopimelic acid (Staneck & Roberts, 1974), mycolic acids (Minnikin et al., 1980), polar lipids (Minnikin et al.,...
Purification of chromosomal DNA was carried out by using the Wizard genomic DNA purification kit (Promega) according to the manufacturer’s instructions. The 16S rRNA gene of strain SST-8T was amplified by PCR as described by Lee et al. (2000a) and was subjected to direct sequence determination using an ABI PRISM BigDye Terminator cycle sequencing kit (Applied Biosystems) and an automatic DNA sequencer (model 3730x; Applied Biosystems). The almost-complete 16S rRNA gene sequence of strain SST-8T was determined (1426 nt), and the results of an initial BLAST search against GenBank sequence data indicated that the organism was related to the genus *Brevibacterium* of the family *Brevibacteriaceae*. Multiple alignment of the sequences was performed by using the CLUSTAL X program (Thompson et al., 1997) and then manually optimized following the secondary structure of the bacterial 16S rRNA gene. Phylogenetic analyses were performed using three tree-making algorithms, namely the neighbour-joining (Saitou & Nei, 1987), maximum-likelihood (Felsenstein, 1981) and maximum-parsimony (Fitch, 1971) methods. A phylogenetic tree was reconstructed based on the neighbour-joining method from evolutionary distances calculated according to the method of Jukes & Cantor (1969). Confidence in the tree topology was evaluated by bootstrap analysis (Felsenstein, 1985) of 1000 replicated datasets. The neighbour-joining tree (Fig. 1) showed that strain SST-8T formed an intermediate branch within the radiation of the genus *Brevibacterium*. Evolutionary distances for tree construction were calculated using the Jukes–Cantor coefficient. *Micrococcus luteus* ATCC 381T (M38242) was used as outgroup taxon (not shown). Asterisks indicate that the corresponding branches were also recovered in the maximum-likelihood and maximum-parsimony trees. Numbers at nodes indicate percentages of bootstrap support based on a neighbour-joining analysis of 1000 replicated data-sets. Bar, 1 nucleotide substitution per 100 nucleotides.

**Fig. 1.** A neighbour-joining tree based on 16S rRNA gene sequences showing the phylogenetic position of strain SST-8T within the radiation of the genus *Brevibacterium*. Evolutionary distances for tree construction were calculated using the Jukes–Cantor coefficient. *Micrococcus luteus* ATCC 381T (M38242) was used as outgroup taxon (not shown). Asterisks indicate that the corresponding branches were also recovered in the maximum-likelihood and maximum-parsimony trees. hybridization experiments (Stackebrandt & Goebel, 1994). The DNA G+C content determined for strain SST-8T was 70-7 mol%.

Colonial pigmentation was observed visually and recorded after 5 days growth at 30°C on YM-SW agar. Cell morphology was determined on cultures grown for 6, 12, 16, 24 and 72 h on YE-SW agar at 30°C. Cell suspensions were made in sterile distilled water, stained negatively with India ink and observed by using a light microscope (magnification ×1000). Cell motility was observed under an Olympus light microscope equipped with phase-contrast optics (magnification ×400) and further confirmed by the presence of turbidity throughout the tube including semisolid medium. Temperature for growth was tested at 4, 10, 20, 30, 35, 42, 45 and 55°C. NaCl tolerance was studied on ISP2 medium containing NaCl at final concentrations of 0–15% (w/v). Catalase activity was determined with a 3% (v/v) hydrogen peroxide solution. Oxidase activity was observed by oxidation of N,N,N′,N′-tetramethyl-p-phenylenediamine. The ability of the organism to utilize a variety of substrates as sole carbon source was tested using GP2 microplates of the Microlog system (Biolog; 95 substrates). Cells were grown for 3 days at 30°C on YE-SW agar and suspended in 2% (w/v) sea salts solution (Sigma). An aliquot of the suspension
(150 μl) was transferred to each well, and the plates were incubated for 48 h at 30 °C. Reduction of tetrazolium dye was determined by reading the microtitre plates at 595 nm using the microplate reader. API CORYNE and API ZYM strips (bioMérieux) were used according to the manufacturer’s instructions. Degradation of casein, DL-tyrosine and xanthine was examined using the method described by Gordon et al. (1974). The results of the morphological, cultural and physiological characterization are given in the species description below.

Phenotypic features that can be used to differentiate between the new isolate and its phylogenetic neighbours within the genus Brevibacterium are given in Table 1. The combination of phenotypic and genotypic data supports that strain SST-8T be classified as the type strain of a novel species of the genus Brevibacterium, Brevibacterium samyangense sp. nov.

**Description of Brevibacterium samyangense sp. nov.**

*Brevibacterium samyangense* (sam.yang’en.se. N.L. neut. adj. samyangense of Samyang Beach, Jeju, Republic of Korea, from where the type strain was isolated).

Cells are Gram-positive, catalase-positive, oxidase-negative, motile and non-spore-forming. On YE-SW agar, an apparent rod–coccus growth cycle is observed: after 6 h growth, cells are coccoid, occurring singly or in pairs, with the rare occurrence of short rods; after 12 and 16 h growth, most cells are irregular and slender rods, arranged in V-forms; after 24 and 72 h growth, cells are coccoid, occurring singly, in pairs or in chains. Colonies are opaque, convex, circular and bright yellow in colour with an entire edge. Temperature range for growth is 10–45 °C. No growth is observed at 4 or 55 °C. Growth occurs in the pH range 6·1–10·1, with better growth at higher pH. NaCl tolerance for growth is observed, with good growth at 0–5 %, moderate growth at 6–9 % but only weak growth at 10 or 15 % NaCl. Degradation of DL-tyrosine is observed but not of casein or xanthine. The following substrates are utilized as sole carbon and energy sources for growth in Biolog GP2 tests: β-cyclodextrin, dextrin, glycogen, inulin, mannann, Tweens 40 and 80, N-acetyl-D-glucosamine, N-acetyl-β-D-mannosamine, amygdalin, L-arabinose, D-arabitol, arbutin, D-cellobiose, D-fructose, L-fucose, D-galactose, D-galacturonic acid, α-D-glucose, myo-inositol, α-D-lactose, lactulose, maltose, maltotriose, D-mannitol, D-mannose, D-melezitose, D-d-melibiose, methyl α-D-galactoside, methyl β-D-galactoside, 3-methyl D-glucoside, methyl α-D-glucoside, methyl β-D-glucoside, methyl α-D-mannoside, palatinose, D-psicose, D-rafﬁnose, L-rhamnose, D-ribose, salicin, sedoheptulose, D-sorbitol, stachyose, sucrose, D-tagatose, D-trehalose, turanose, xylitol, D-xylene, acetic acid, α, β- and γ-hydroxybutyric acids, p-hydroxyphenylacetic acid, α-ketoglutaric acid, α-ketovaleric acid, lactamide, D-lactic acid methyl ester, L-lactic acid, L-malic acid, methylpyruvate, monomethylsuccinate, propionic acid, succinamic acid, succinic acid, N-acetyl-D-glutamic acid, L-alaninamide, D- and L-alanine, L-alanylglucose, L-asparagine, L-glutamic acid, glycyll L-glutamic acid, L-proglyutamic acid, L-serine, putrescine, adenosine, 2′-deoxyadenosine, inosine, thymidine, uridine, adenosine 5′-monophosphate, thymidine 5′-monophosphate, uridine 5′-monophosphate, α-D-glucose 1-phosphate, D-glucose 6-phosphate and D-L-xylitol phosphate. The following substrates in the Biolog GP2 system are not utilized: cyclodextrin, gentiobiose, D-glucosamine, D-malic acid, 2,3-butanediol, glycerol and D-fructose 6-phosphate. In the API CORYNE system, pyrazinamidase, pyrrolidonyl arylamidase, alkaline phosphatase, β-galactosidase and α-glucosidase are positive. Nitrate reduction, β-glucuronidase, N-acetyl-β-glucosaminidase, β-glucosidase (aesculin hydrolysis), urease, gelatin

Table 1. Differential phenotypic characteristics of strain SST-8T and its phylogenetic relatives in the genus Brevibacterium

Taxa: 1, strain SST-8T; 2, Brevibacterium avium (data from Pascal & Collins, 1999); 3, Brevibacterium luteolum (Wauters et al., 2003); 4, Brevibacterium mcbrellneri (McBride et al., 1993); 5, Brevibacterium otitidis (Pascual et al., 1996); 6, Brevibacterium paucivorans (Wauters et al., 2001). Characteristics are recorded as: +, positive; W, weakly positive; –, negative; ND, no data available; ?, conflicting results between data given in species description and table of differential characteristics.
hydrolysis and fermentation of D-ribose, D-xylene, D-mannitol, D-lactose and glycerogen are negative. Acid production from D-glucose, D-maltose and sucrose are weakly positive. In additional tests with the API ZYM system, esterase (C4), esterase lipase (C8), leucine arylamidase, trypsin and naphthol-AS-BI-phosphohydrolase are positive. Valine arylamidase and cystine arylamidase are weakly positive. The following give negative responses: lipase (C14), α-chymotrypsin, acid phosphatase, x-galactosidase, β-gluconidase, β-glucosidase, N-acetyl-β-glucosaminidase, x-mannosidase and x-fucosidase. The phospholipid profiles contain diphasphatidylglycerol. Mycolic acids are not present. The major cellular fatty acids are anteiso-C17:0, anteiso-C15:0 and iso-C15:0. The G + C content of the DNA is 70–7 mol%.

The type strain, SST-8T (=NRRL B-41420T = KCCM 42316T), was isolated from sand sediment of Samyang Beach, Jeju Island, Republic of Korea.

Acknowledgements

This work was supported by the 21C Frontier Microbial Genomics and Application Center Program, Ministry of Science & Technology, Republic of Korea. I am grateful to H. L. Yang for fatty acid analysis and D. W. Lee for the determination of DNA G + C content.
