Four alkaligenous, moderately halotolerant strains, designated ge09, ge10T, ge14T and ge15, were isolated from the internal tissue of ginseng root and their taxonomic positions were investigated by using a polyphasic approach. Cells of the four strains were Gram-positive-staining, non-motile, short rods. Phylogenetic analysis based on 16S rRNA gene sequences showed that strains ge09 and ge10T formed one cluster and strains ge14T and ge15 formed another separate cluster within the genus Bacillus. 16S rRNA gene sequence similarities with type strains of other Bacillus species were less than 97%. Levels of DNA–DNA relatedness among the four strains showed that strains ge09 and ge10T and strains ge14T and ge15 belonged to two separate species; the mean level of DNA–DNA relatedness between ge10T and ge14T was only 28.7%. Their phenotypic and physiological properties supported the view that the two strains represent two different novel species of the genus Bacillus. The DNA G+C contents of strains ge10T and ge14T were 49.9 and 49.6 mol%, respectively. Strains ge10T and ge14T showed the peptidoglycan type A4α L-Lys–D-Glu. The lipids present in strains ge10T and ge14T were diphosphatidylglycerol, phosphatidylglycerol, a minor amount of phosphatidylcholine and two unknown phospholipids. Their predominant respiratory quinone was MK-7. The fatty acid profiles of the four novel strains contained large quantities of branched and saturated fatty acids. The predominant cellular fatty acids were iso-C15:0 (42.5%), anteiso-C15:0 (22.2%), anteiso-C17:0 (7.3%) and C16:1ω7c alcohol (5.7%) in ge10T and iso-C15:0 (50.7%) and anteiso-C15:0 (20.1%) in ge14T. On the basis of their phenotypic properties and phylogenetic distinctiveness, two novel species of the genus Bacillus are proposed, Bacillus beijingensis sp. nov. (type strain ge10T = DSM 19037T = CGMCC 1.6762T) and Bacillus ginsengi sp. nov. (type strain ge14T = DSM 19038T = CGMCC 1.6763T).

The genus Bacillus contains aerobic or facultatively anaerobic, Gram-positive, sporulating, rod-shaped bacteria that are ubiquitous in nature. Bacillus species have a wide range of physiological adaptations that enable them to survive or thrive in harsh environments, ranging from desert sands and hot springs to Arctic soils and from freshwater to marine sediments. Some of them are alkaliphilic and halotolerant (Nielsen et al., 1995; Muntyan et al., 2002; Nogi et al., 2005; Pollock et al., 2007). In this paper, the taxonomic characterization of four novel bacterial strains (ge09, ge10T, ge14T and ge15) isolated from the internal tissue of ginseng roots is reported. 16S rRNA gene sequencing, DNA–DNA relatedness studies and phenotypic testing showed that these four bacterial isolates represent two novel species of the genus Bacillus.
Strains ge09, ge10<sup>T</sup>, ge14<sup>T</sup> and ge15 were isolated originally on Luria–Bertani (LB) agar plates that had been seeded with a tissue suspension of ginseng roots and incubated at 28 °C for 3 days. Healthy 3-year-old ginseng roots were sampled by the Institute of Medicinal Plant Development, Chinese Academy of Medical Sciences in Beijing, China. The root tissue suspension was prepared according to the following procedure (Qiu et al., 2007). Roots were separated from the soil, washed with tap water and surface-sterilized with 75% ethanol for 3 min and 2.6% sodium hypochlorite solution for 3–5 min followed by rinsing with sterile double-distilled water (ddH<sub>2</sub>O). The surface-sterilized root mass was pulverized in a ceramic mortar and diluted with sterile ddH<sub>2</sub>O using the standard dilution plating technique. Twenty-eight colonies formed on one of the plates. 16S rRNA gene sequence analysis revealed that four of them (strains ge09, ge10, ge14 and ge15) probably represented novel species of the genus Bacillus. The four strains were maintained on LB agar slants at 4 °C and as a glycerol suspensions (20%, v/v) at −20 °C. Biomass for chemotaxonomic and molecular systematic studies was prepared by growing the strains in shake flasks of LB broth containing (1<sup>−1</sup>) 10 g casein peptone, 5 g yeast extract and 10 g NaCl; pH 7.0] at 28 °C for 3–5 days. Cells were harvested by centrifugation, washed with ddH<sub>2</sub>O and freeze-dried before use in chemical studies.

Colonial properties of the isolates were observed on LB agar. Cell morphology was examined by light microscopy and transmission electron microscopy (TEM; Hitachi H-600). For visualization of flagella, cells were mounted on copper grids, negatively stained with 1% (w/v) uranyl acetate for 15 min and then subjected to TEM at 100 kV. To facilitate sporulation, MnSO<sub>4</sub> (50 mg l<sup>−1</sup>) was added to the medium. Spore formation was determined by staining with malachite green as described previously by Gerhardt et al. (1994). Strains were also observed by phase-contrast microscopy (DMRE; Leica) using an oil-immersion objective (×100) to ascertain shape and motility. Gram staining was carried out using a standard procedure (Hucker & Conn, 1923).

The catalase reaction, anaerobic growth, Voges–Proskauer test, resistance to lysozyme, growth in NaCl, growth at pH 5.7, hydrolysis of starch, utilization of citrate and propionate, production of indole, deamination of phenylalanine, decomposition of casein and liquefaction of gelatin were examined by the methods of Gordon et al. (1973). Growth was tested at different temperatures (4–50 °C) and pH (5.0–12.0) in LB medium. Utilization of a variety of substrates as sole carbon sources was tested using the Biolog system (Gram Positive Identification Test Panel; GP2 MicroPlate).

Purified peptidoglycan preparations were obtained after disruption of cells by shaking with glass beads and subsequent trypsin digestion according to the method of Schleifer (1985). Amino acids and peptides in cell-wall hydrolysates were analysed by two-dimensional ascending TLC on cellulose plates by using previously described solvent systems (Schleifer, 1985). The molar ratios of the amino acids were determined by GC and GC-MS of N-heptafluorobutyryl amino acid isobutyl esters (MacKenzie, 1987). Cellular menaquinones were extracted and purified as described by Collins (1985) and analysed by HPLC (Wu et al., 1989). Polar lipids were extracted and analysed by two-dimensional TLC according to Tindall (1990). For determination of fatty acid composition, the four novel strains were cultivated on trypticase soy broth agar containing (1<sup>−1</sup>) 30 g trypticase soy broth and 15 g agar (Difco]) at 28 °C for 24 h. Fatty acids were extracted, purified, methylated, identified and quantified by GC with the standard Microbial Identification system (MIDI) (Sasser, 1990; Kämpfer & Kroppenstedt, 1996).

A loop of biomass was scraped off the agar plate, suspended in 20 μl ddH<sub>2</sub>O and lysed by boiling for 10 min and freezing for 5 min. Following centrifugation, the supernatant was used as the template for PCR. The 16S rRNA gene was amplified using the universal primers 27F (5′-AGAGTTTGATCCTGGCTCAG-3′) and 1492R (5′-GGTTACCTTGTGACTGTT-3′) (Lane, 1991). The amplified products were purified and cloned into vector Top10 (Tiangen) for sequence determination. Automated sequencing was performed by using an ABI BigDye Primer cycle sequencing ready reaction kit and an Applied Biosystems 3730 DNA sequencer. The sequencing primers were SP6 (5′-ATTTAGTGACTAGATACAG-3′) and T7 (5′-TAATACGACTCATATAGAGG-3′). The 16S rRNA gene sequences of the four novel bacterial strains (ge09, 1551 bp; ge10<sup>T</sup>, 1512 bp; ge14<sup>T</sup>, 1512 bp; ge15, 1552 bp) and those of other Bacillus species retrieved from GenBank were aligned using the program CLUSTAL_X v. 1.8 (Thompson et al., 1997). Three tree-making algorithms, namely the neighbour-joining (Saitou & Nei, 1987), maximum-parsimony (Eck & Dayhoff, 1966; Fitch, 1971) and minimum evolution (Rzhetsky & Nei, 1992) methods from the MEGA4 package (Tamura, et al., 2007), were used to infer phylogenetic evolutionary trees.

Preparation of genomic DNA was carried out according to the method of Marmur (1961). The DNA G+C content was determined using the thermal denaturation method (Marmur & Doty, 1962) with Escherichia coli K-12 as a control. Levels of DNA–DNA relatedness among the four strains were determined by using the reassociation rate method at a hybridization temperature of 60 °C (Dong et al., 2000).

Comparisons with GenBank sequences revealed that the 16S rRNA gene sequences of the four isolates did not match those of any known bacterium. The bacterium with the greatest pairwise similarity to strain ge10<sup>T</sup> was the type strain of Bacillus pocheonensis (96.1% 16S rRNA gene sequence similarity), whereas the type strain of Bacillus furmarioli most closely matched strain ge14<sup>T</sup> (96.0% similarity). A comparative 16S rRNA gene sequence
D-Asp. The lipids present in strains ge10T and ge14T were more than 98 %. The level of DNA–DNA relatedness between ge09 and ge10T was 86.4 % and that between ge14T and ge15 was 70.7 %. The mean level of DNA–DNA relatedness between strains ge10T and ge14T (28.7 %) was low enough to distinguish these two strains at the species level. A phylogenetic tree (Fig. 1) constructed using the neighbour-joining method suggested that strains ge09, ge10T, ge14T and ge15 are members of the genus Bacillus, representing two distinct species. The phylogenetic trees inferred by maximum-parsimony and the minimum evolution method showed relationships similar to those presented in Fig. 1.

Morphological, cultural and biochemical characteristics of strains ge09, ge10T, ge14T and ge15 are given in the species descriptions and in Table 1 and Supplementary Table S1 (available in IJSEM Online). Endospores were not observed in the novel isolates; this has also been found in some other bacilli, e.g. endospore formation has not been detected in Bacillus foraminis (Tiago et al., 2006) or Bacillus thermoamylolovorans (Combet-Blanc et al., 1995). Strains ge10T and ge14T both showed peptidoglycan type A41-L-Lys–D-Glu (A11.33 according to http://www.dsmz.de/microorganisms/main.php?content_id=35). In the case of strain ge14T, a small portion of D-Glu in the interpeptide bridge was replaced by D-Asp. The lipids present in strains ge10T and ge14T were diphosphatidylglycerol, phosphatidylglycerol, a minor amount of phosphatidylcholine and two unknown phospholipids.

Strain ge14T grew only slowly on LB agar when compared with the other strains. Capsules around the cells of strain ge14T that could not be detected in the other strains were observed by light and electron microscopy. In addition, the four novel strains were alkaligenous when cultivated in LB medium. The pH of medium increased to more than 8.0 after inoculation with the novel strains. MK-7 was the major menaquinone component, which is in agreement with the description of members of the genus Bacillus. The bacterial isolates were tested with the Biolog system (Gram Positive Identification Test Panel; GP2 MicroPlate) to assay their utilization of carbon sources (see Supplementary Table S1). The fatty acid profiles of the isolates were also compared (Supplementary Table S2). As with related Bacillus species, the fatty acid profiles of the four novel strains contained large quantities of branched and saturated fatty acids, especially iso-C15:0 and anteiso-C15:0.

According to their biochemical characteristics and cellular fatty acid profiles, it was demonstrated that the four isolates represent two different species; this was confirmed by the results of 16S rRNA gene sequence comparisons and DNA–DNA hybridization data. Although a comparative 16S rRNA gene similarity analysis revealed that strain ge10T was most closely related to strain ge14T (98.49 %), DNA–DNA hybridization results supported species differentiation of the two strains. There are many examples of Bacillus species having pairwise sequence similarities of >98.5 % (Ko et al., 2006), but with DNA–DNA relatedness values far below the 70 % threshold for delineation of species (Wayne et al., 1987).

On the basis of the above biochemical data, cellular fatty acid compositions and molecular phylogenetic results, strains ge10T and ge14T represent two novel species of Bacillus, for which the names Bacillus beijingensis sp. nov. and Bacillus ginsengi sp. nov., respectively, are proposed.

**Description of Bacillus beijingensis sp. nov.**

_B. beijingensis_ (bei.jing.en’sis. N.L. masc. adj. _beijingensis_ of Beijing, where the type strain was isolated).

Cells are alkaligenous, Gram-positive-staining, strictly aerobic, non-motile (non-flagellated), short rods to almost spherical in shape (1.0–1.5 × 0.5–0.8 μm). Endospores are not observed on LB agar supplemented with MnSO₄. Cells are not killed by heating at 80 °C for 10 min. After 24–48 h growth on LB agar, colonies are up to 3–7 mm in diameter, circular and raised, with entire edges and an off-white to...
Bacillus ginsengi sp. nov.

Bacillus ginsengi (gin.sen’gi. N.L. gen. n. ginsengi of ginseng, the source of the type strain).

Cells are alkaliogenous, Gram-positive-staining, strictly aerobic, non-motile (non-flagellated), short rods to almost spherical in shape (1.1–1.5 \( \times \) 0.9–1.3 \( \mu \)m). Endospores are not observed on LB agar supplemented with MnSO_4. Capsules are observed by light and electron microscopy. Cells are not killed by heating at 80 °C for 10 min. After 24–48 h growth on LB agar, colonies are up to 2–3 mm in diameter, circular and raised, with entire edges and an off-white to yellow, opaque, glossy appearance. Cells grow slowly on LB agar and in LB medium. Usually, it is necessary to cultivate cells for more than 5 days in shake flasks of LB broth at 28 °C to reach the concentration required for chemotaxonomic studies. Optimum growth temperature is 30 °C; grows at 4–45 °C. The pH range for growth is 6.0–11.0; optimum pH is 7.0–8.0. Can grow in 0–10% NaCl. Casein, gelatin and aesculin are hydrolysed; tests for catalase, oxidase and nitrate reduction are positive. Negative for utilization of citrate and propionate, hydropysis of starch and Tween 80, phenylalanine deaminase, indole production and Voges–Proskauer and methyl red positive. Arginine dihydrolase activity is variable. Sensitive to lysozyme. The medium pH changes gradually from 7.0 to 8.5 during cultivation. Acetic acid, 2-ketovaleric acid, pyruvic acid methyl ester, pyruvic acid, L-alanine, L-alanyl glycine, L-glutamic acid, adenosine, 2'-deoxyadenosine, inosine, thymidine, L-malic acid, succinic acid mono-methyl ester, succinic acid, succinic acid and L-serine are used as sole carbon sources for energy and growth. Utilization of \( \beta \)-cyclodextrin, dextrin, glycogen, Tween 40, N-acetyl-D-glucosamine, L-arabinose, D-arabitol, D-fructose, myo-inositol, maltose, 3-methyl glucose, methyl \( \alpha \)-D-glucoside, methyl \( \beta \)-D-glucoside, methyl \( \alpha \)-D-mannoside, stachyose, turanose, xylitol, \( \beta \)-hydroxybutyric acid, \( \alpha \)-ketovaleric acid, lactamide, D-lactic acid methyl ester, D-malic acid, N-acetyl-L-glutamic acid, L-alaninamide, D-alanine, glycy l-L-glutamic acid, putrescine, glycerol and uridine as sole carbon sources is variable (Biolog). The major isoprenoid quinone is MK-7. The predominant cellular fatty acids are \( \text{iso-C}_{15:0}, \text{anteiso-C}_{15:0}, \text{anteiso-C}_{17:0} \) summed feature 4 (iso-C_{17:1} \text{I and/or anteiso-C}_{17:1} B) and \( \text{C}_{16:1} \text{a9c} \) alcohol.

The type strain is ge10^T (=DSM 19037T =CGMCC 1.6762T), isolated from the internal tissue of ginseng roots cultivated in Beijing, China. The DNA G+C content of strain ge10^T is 49.9 mol%. Strain ge09 is a second strain of the species.
