Description of *Leifsonia kafniensis* sp. nov. and *Leifsonia antarctica* sp. nov.

Pavan Kumar Pindi,† K. Hara Kishore,† G. S. N. Reddy and S. Shivaji

Centre for Cellular and Molecular Biology, Uppal Road, Hyderabad 500 007, India

Strains KFC-22\(^T\) and SPC-20\(^T\) are yellow-pigmented, Gram-positive, aerobic, non-motile, rod-shaped bacteria that were isolated from a soil sample near the Kafni glacier in the Himalayan mountain ranges in India, and from a spade core sediment sample from the Antarctic Ocean at Larsemann Hill, respectively. In both cases, the cell-wall peptidoglycan contained 2,4-diaminobutyric acid as the diamino acid, anteiso-C\(_{15:0}\); anteiso-C\(_{17:0}\) and iso-C\(_{16:0}\) were the predominant fatty acids and MK-11 was the major isoprenoid quinone in the cell membrane. On the basis of the above-mentioned characteristics, both strains can be assigned to the genus *Leifsonia*. The strains share 16S rRNA gene sequence similarity of 97.7% and DNA relatedness of only 10%, indicating that they represent different species. A BLAST analysis indicated that *Leifsonia pindariensis* PON10\(^T\) was the closest phylogenetic neighbour of strains SPC-20\(^T\) and KFC-22\(^T\), showing 16S rRNA gene sequence similarities of 97.3 and 97.7%, respectively. However, at the whole-genome level, strains KFC-22\(^T\) and SPC-20\(^T\) shared 42 and 11% DNA–DNA relatedness, respectively, with *L. pindariensis* PON10\(^T\). In addition, both strains exhibited several phenotypic differences with respect to *L. pindariensis*. Thus, on the basis of the differences that the two strains exhibited with respect to *L. pindariensis*, both were identified as representing novel species of the genus *Leifsonia*, for which the names *Leifsonia kafniensis* sp. nov. (type strain KFC-22\(^T\) = NCCB 100216\(^T\) = LMG 24362\(^T\)) and *Leifsonia antarctica* sp. nov. (type strain SPC-20\(^T\) = NCCB 100227\(^T\) = LMG 24541\(^T\)) are proposed.

---

The genus *Leifsonia* was originally described by Evtushenko *et al.* (2000) and its description was emended by Reddy *et al.* (2008). The genus includes bacteria that are Gram-positive, non-spore-forming, rod-shaped (or filamentous), obligately aerobic and catalase-positive. The cell-wall peptidoglycan is of the B type and contains 2,4-diaminobutyric acid as the diamino acid. MK-11 is the major menaquinone. Phosphatidylglycerol and diphosphatidylglycerol are the principal phospholipids and the major fatty acids are anteiso-C\(_{15:0}\); anteiso-C\(_{17:0}\) and iso-C\(_{16:0}\). The G+C content of the DNA ranges from 66 to 73 mol%. At the time of writing, 11 species have been described (Evtushenko *et al.*, 2000; Leifson, 1962; Davis *et al.*, 1984; Suzuki *et al.*, 1999; Reddy *et al.*, 2003; Qiu *et al.*, 2007; Reddy *et al.*, 2008; Dastager *et al.*, 2008, 2009). Of the 11 reported species, four (*Leifsonia rubra*, *Leifsonia aurea*, *Leifsonia ginsengi* and *Leifsonia pindariensis*) are psychrotolerant, having a minimum growth temperature of 0–4°C; the rest are mesophilic. In the present study, two novel psychrotolerant species are described. The strains (designated KFC-22\(^T\) and SPC-20\(^T\)) representing these two novel species were isolated from two different cold habitats, namely the Kafni glacier of the Himalayas and a sediment from Antarctica, and were characterized using a polyphasic taxonomic approach.

Strain KFC-22\(^T\) was isolated from a soil sample collected close to the Kafni glacier, at an altitude of 3500 m in the Himalayan mountain ranges in India. Strain SPC-20\(^T\) was isolated from a spade core sediment from the Antarctic Ocean near the Larsemann Hill area (69° 21.950′ S 76° 06.296′ E). A sample of approximately 200 mg was suspended in 5 ml 0.9% NaCl, subjected to shaking at 3000 r.p.m. for 1 h at room temperature, allowed to settle and plated (100 μl) either on Luria–Bertani agar (for KFC-22\(^T\)) or nutrient agar (for SPC-20\(^T\)) (Shivaji *et al.*, 2005). On the basis of colony morphology, two yellow-pigmented strains (KFC-22\(^T\) and SPC-20\(^T\)) were purified and main-
tained on nutrient agar plates (containing 0.3% beef extract, 0.5% peptone, 0.8% sodium chloride and 1.5% agar). Morphology was studied using light microscopy and transmission electron microscopy as described previously (Reddy et al., 2006) and motility was assessed on 0.4% nutrient agar plates. Growth, biochemical characteristics (Lányi, 1987; Smibert & Krieg, 1994), carbon assimilation and the sensitivity of the cultures to different antibiotics were determined by using previously described methods (Reddy et al., 2004). Biochemical characteristics were determined using the Hi25 Enterobacteriaceae identification kit (catalogue no. KB003; Himedia) and parts A, B and C of the HiCarbohydrate kit (catalogue no. KB009; Himedia), according to the manufacturer’s protocols.

For quantitative analysis of whole-cell fatty acids, cells of KFC-22T and SPC-20T were grown on tryptic soy agar medium (Reddy et al., 2008) at 25 °C for 2 days and analysed using the Sherlock Microbial Identification System (MIDI), according to the protocols described by Agilent Technologies. Lipids and pigments were extracted and analysed as described previously (Reddy et al., 2007). Peptidoglycan and cell-wall sugars were prepared and analysed according to the method of Komagata & Suzuki (1987). Isoprenoid quinones were extracted according to the method of Collins et al. (1977) and were separated using HPLC with an isoocratic solvent system consisting of methanol/isopropyl ether (3:1) (Tamaoka et al., 1983; Tamaoka, 1986).

DNA from strains KFC-22T and SPC-20T was isolated according to the method of Marmur (1961) and the 16S rRNA gene was PCR-amplified and sequenced as described previously (Reddy et al., 2000). The almost-complete sequences (1518 and 1516 nt for KFC-22T and SPC-20T, respectively) of the 16S rRNA genes were aligned with closely related sequences belonging to the genus Leifsonia, using CLUSTAL W (Thompson et al., 1994). Pairwise evolutionary distances were computed using the DNADIST program with Kimura’s two-parameter model (Kimura, 1980). Phylogenetic trees were constructed using four different tree-making algorithms, namely neighbour joining, minimum evolution, the unweighted pair group method with arithmetic averages and maximum parsimony, by using the MEGA3 software package (Kumar et al., 2004). Bootstrap analysis, based on 1000 replicate datasets, was performed to assess stability among the clades recovered in the phylogenetic tree.

Strains KFC-22T and SPC-20T were assigned to the genus Leifsonia on the basis of characteristics described for the genus Leifsonia (Evtushenko et al., 2000; Reddy et al., 2008). Both isolates consisted of Gram-positive, catalase-positive, curved rods that contained 2,4-diaminobutyric acid in the peptidoglycan, had MK-11 as the major menaquinone, contained phosphatidylglycerol and diphasphatidylglycerol as the polar lipids and had high levels of fatty acids anteiso-C15:0, anteiso-C17:0 and iso-C16:0. In addition, the BLAST sequence similarity results, based on 16S rRNA gene sequences, also supported the affiliation of KFC-22T and SPC-20T to the genus Leifsonia (Evtushenko et al., 2000; Suzuki et al., 1999; Reddy et al., 2008). The two strains shared a base-to-base 16S rRNA gene sequence similarity of 97.7% (Supplementary Table S1, available in IJSEM Online) and a DNA–DNA relatedness of approximately 10%. They also exhibited many phenotypic differences (Table 1), supporting their assignment to separate novel species. Strains KFC-22T and SPC-20T exhibited 16S rRNA gene sequence similarity of 95.0–98.0% with respect to representatives of recognized species of the genus Leifsonia (Supplementary Table S1). The other phylogenetically related genera are Subtercolha (96.0% sequence similarity) (Männistö et al., 2000), Okibacterium (96.0–97.0%) (Evtushenko et al., 2002), Salinibacterium (96.0%) (Han et al., 2003), Rhodoglobus (95.0–96.0%) (Sheridan et al., 2003), Plantibacter (96.0–97.0%) (Behrendt et al., 2002), Agrococcus (96.0–97.0%) (Groth et al., 1996) and Agreia (96.0–97.0%) (Evtushenko et al., 2001). Although the 16S rRNA gene sequence similarities were high with respect to some members of these genera, phylogenetic analyses (Fig. 1) showed that the two strains should be assigned to the genus Leifsonia. Interestingly, phylogenetic analysis based on neighbour joining, minimum evolution and maximum parsimony (DNAPARS) algorithms indicated that the genus Leifsonia is polyphyletic, with the species clustering into three clades (Fig. 1). Despite the polyphyletic nature of the genus, all of the species share common generic characteristics, thus overcoming the ambiguity caused by the phylogenetic analyses. Of all the species of the genus Leifsonia, it was the type strain of the recently described species L. pindariensis (Reddy et al., 2008) with which KFC-22T and SPC-20T exhibited the highest 16S rRNA gene sequence similarity (97.7 and 97.3%, respectively). This was further confirmed by phylogenetic analyses using minimum evolution and the unweighted pair group method with arithmetic averages, in which strains KFC-22T and SPC-20T clustered with L. pindariensis PON10T at a bootstrap value greater than 50%; with neighbour joining, the bootstrap value was 46%. Phylogenetic trees constructed using Arthrobacter globiformis DSM 20124T (GenBank accession no. X80736), Corynebacterium diphtheriae DSM 9607T (GenBank accession no. X80736), Bacillus subtilis DSM 10T (AJ276351) and Agrococcus jenensis DSM 9580T (X92492) as outgroups showed no change in the topology of the trees (not shown). This suggests that the two isolates could be strains of previously described species. However, strains KFC-22T and SPC-20T showed DNA–DNA relatedness of 42 and 11%, respectively, with L. pindariensis PON10T, clearly showing that both strains represent novel species. In addition, KFC-22T and SPC-20T exhibited phenotypic differences with respect to L. pindariensis PON10T (Table 1). On the basis of the above characteristics, strains KFC-22T and SPC-20T represent novel species, for which the names Leifsonia kafniensis sp. nov. and Leifsonia antarctica sp. nov., respectively, are proposed.
Leifsonia kafniensis (kaf.ni.en’sis. N.L. fem. adj. kafniensis pertaining to the Kafni glacier in the Himalayas of India, where the type strain was isolated).
Cells are Gram-positive, non-motile, aerobic, rod-shaped (0.4 × 1.5 μm) and yellow-pigmented. Positive for catalase and aesculin hydrolysis, but negative for lipase, hydrolysis of casein and starch, H₂S production, lysine, arginine and ornithine decarboxylases, indole production, the methyl red test, the Voges–Proskauer test and for phenylalanine deamination. Does not produce acid from myo-inositol, D-rhamnose or D-xylose. Utilizes glycerol, but not creatinine, L-histidine, hydroxyproline, L-leucine, L-methionine, sucrose, trehalose, L-tryptophan or D-xylose. The type strain is sensitive to the following antibiotics (μg per disc): bacitracin (10), carbenicillin (100), cefotaxime (30), chloramphenicol (30), erythromycin (15), gentamicin-G (30), oleandomycin (15), penicillin G (10), rifampicin (30), spectinomycin (100), streptomycin (10) and tetracycline (30); resistant to colistin (10 μg per disc). Contains three unknown lipids, with Rₖ values of 0.63, 0.66 and 0.73, in addition to the lipids listed in Table 1. The other characteristics of the species are listed in Table 1. Absorption maxima of the yellow pigment in methanol at 350, 360, 370, 430, 440, 450, 470 and 475 nm. The other characteristics of the species are listed in Table 1. Absorption maxima of the yellow pigment in methanol at 360, 370, 440, 450, 470 and 480 nm. The other characteristics of the species are listed in Table 1. The type strain, SPC-20 T (= NCCB 100216 T = LMG 24541 T), was isolated from a soil sample collected close to the Kafni glacier in the Himalayan mountain ranges of India.

**Description of Leifsonia antarctica** sp. nov.

*Leifsonia antarctica* (an.tarc’ti.ca. L. fem. adj. antarctica southern, by extension pertaining to the Antarctic, where the type strain was isolated).

Cells are Gram-positive, non-motile, aerobic, rod-shaped (0.5 × 0.7 μm) and pale-yellow-pigmented. Positive for catalase and aesculin hydrolysis, but negative for lipase, hydrolysis of casein and starch, H₂S production, lysine, arginine and ornithine decarboxylases, indole production, the methyl red test, the Voges–Proskauer test and for phenylalanine deamination. Does not produce acid from myo-inositol, D-rhamnose or D-xylose. Utilizes glycerol, but not creatinine, L-histidine, hydroxyproline, L-leucine, L-methionine, sucrose, trehalose, L-tryptophan or D-xylose.

The type strain is sensitive to the following antibiotics (μg per disc): bacitracin (10), carbenicillin (100), cefotaxime (30), chloramphenicol (30), erythromycin (15), gentamicin-G (30), oleandomycin (15), penicillin G (10), rifampicin (30), spectinomycin (100), streptomycin (10) and tetracycline (30); resistant to colistin (10 μg per disc). Contains three unknown lipids, with Rₖ values of 0.63, 0.66 and 0.73, in addition to the lipids listed in Table 1. The other characteristics of the species are listed in Table 1. Absorption maxima of the yellow pigment in methanol at 350, 360, 370, 430, 440, 450, 470 and 475 nm.

The type strain, SPC-20 T (= NCCB 100216 T = LMG 24541 T), was isolated from a sediment from the Antarctic Ocean, near the Larsemann Hill area of Antarctica.
