A strictly anaerobic bacterial strain, 7401987T, was isolated from a human brain abscess sample. Cells were Gram-negative, non-spore-forming, coccoid to rod-shaped and motile by flagella in a lophotrichous arrangement. The isolate was saccharolytic and the major cellular fatty acids were anteiso-C₁₅:0 (28.2%), C₁₆:0 (18.0%), iso-C₁₅:0 (12.3%) and iso-C₁₇:0 3-OH (11.7%). 16S rRNA gene sequence comparisons showed that the isolate was distantly related to members of the genera *Bacteroides* (<83.6% similarity), *Parabacteroides* (<79.9% similarity), *Tannerella* (<79.8% similarity), *Dysgonomonas* (<79.6% similarity), *Porphyromonas* (<79.3% similarity) and *Prevotella* (<78.9% similarity). The low 16S rRNA gene sequence similarity values and physiological and biochemical characteristics differentiated strain 7401987T from all known species and indicate that our isolate represents a novel species in a new genus within the phylum *Bacteroidetes*. The name *Phocaeicola abscessus* gen. nov., sp. nov. is proposed; the type strain of *Phocaeicola abscessus* is 7401987T (=CCUG 55929T =CSUR P22T =DSM 21584T).

A 76-year-old woman underwent neurosurgical intervention after cancer of the face. Over a period of 3 days, she developed fever, consciousness alterations and aphasia. Magnetic resonance imaging and computerized tomography revealed a left frontal brain abscess with oedema. One day later, the patient underwent drainage of the abscess. A pus specimen recovered from the patient was sent to our laboratory in aerobic and anaerobic BACTEC bottles for culture and molecular investigations.

Supernatant from anaerobic BACTEC bottles was inoculated into Schaedler broth supplemented with K3 (bioMérieux). To eradicate rapidly growing bacteria that would outgrow anaerobes, liquid medium was supplemented with antibiotics. Four tube types were prepared: the first tube was supplemented with 0.0075 g vancomycin l⁻¹; the second tube was supplemented with 0.10 g kanamycin...
l⁻¹; the third tube was supplemented with both vancomycin and kanamycin; and no antibiotic was added to the fourth tube. Tubes were incubated at 37 °C and examined daily for bacterial growth. When the media were turbid, they were used to inoculate 5% sheep blood agar and chocolate agar plates (bioMérieux), which were then incubated anaerobically at 37 °C. Plates were inspected every 5 days. Strain 7401987ᵀ was recovered after 10 days incubation under anaerobic conditions at 37 °C from chocolate agar that had been inoculated with a sample from the kanamycin-supplemented tube.

Growth was tested on chocolate agar, 5% blood agar, tryptic soy agar and 5% blood Schaedler agar (bioMérieux). Growth was positive only on chocolate agar plates after 5 days incubation; growth was not observed after 15 days on the other media tested. Surface colonies on chocolate agar after 7 days incubation at 37 °C under anaerobic conditions were white, circular, regular, smooth, shiny, convex and 1 mm in diameter. Growth was also tested in BYP medium developed in our laboratory. The composition of the medium was as follows: brain-heart infusion agar (10 g l⁻¹), yeast extract (10 g l⁻¹), meat peptone (5 g l⁻¹), casein peptone (5 g l⁻¹), starch (2 g l⁻¹), d-glucose (2.5 g l⁻¹), NaCl (2.5 g l⁻¹), KH₂PO₄ (1 g l⁻¹), Na₃HPO₄ (3 g l⁻¹), haemin (0.025 g l⁻¹), vitamin K₁ (0.01 g l⁻¹) and a vitamin/mineral mixture comprising vitamin A (500 IU l⁻¹), vitamin D₃ (40 IU l⁻¹), vitamin B₁ (2 mg l⁻¹), vitamin B₂ (2 mg l⁻¹), vitamin B₆ (0.2 mg l⁻¹), vitamin B₁₂ (0.6 mg l⁻¹), vitamin B₉ (2 mg l⁻¹), vitamin C (6 mg l⁻¹), vitamin E (5 mg l⁻¹), folic acid (0.3 mg l⁻¹), calcium pantothenate (3 mg l⁻¹), iron (ferrous fumarate; 1.5 mg l⁻¹), magnesium sulfate (0.5 mg l⁻¹) and calcium phosphate (10 mg l⁻¹).

Growth was positive in this medium after 5 days incubation at 37 °C in an anaerobic atmosphere. Growth of the isolate was tested under anaerobic and microaerophilic conditions generated with the GENbag anaer and GENbag microaer systems, respectively (bioMérieux). Growth was also tested in the presence of air and 5% CO₂. The strain was strictly anaerobic and did not grow in air, 5% CO₂ or microaerophilic atmospheres. Different growth temperatures (25, 30, 37, 45 and 50 °C) were tested; growth occurred between 30 and 37 °C. Optimum growth was observed at 37 °C.

The size and ultrastructure of the cells were determined by transmission electron microscopy. Cells were grown on Schaedler broth for 7 days. A bacterial suspension was prefixed in 5% (v/v) glutaraldehyde in phosphate buffer (Gibco) for at least 1 h at room temperature, washed in the same buffer and stained with 1% (w/v) phosphotungstic acid. Samples were examined on a Morgagni 268D (Philips) electron microscope at an operating voltage of 60 kV. Coccoid and rod-shaped bacteria were observed. After 7 days growth in Schaedler broth, 7% cells were rods (1.7–0.4 μm wide and 1.2–6.5 μm long) and 93% cells were coccoid (0.3–0.6 μm wide and 0.4–0.9 μm long) (Fig. 1). Catalase activity, determined by the ID colour catalase test kit (bioMérieux), was negative. Oxidase activity was negative as determined by applying cells to moistened discs that were impregnated with dimethyl-p-phenylene diamine (bioMérieux). A mobility test, performed after 8 days incubation in Schaedler broth, was positive. API ZYM, API Rapid ID 32A and API 50CH strips combined with API 50CH/E (all bioMérieux) were used for biochemical tests according to the manufacturer’s instructions. Additional biochemical characteristics were also obtained using the Biolog system. Bacterial growth was observed on chocolate agar plates (bioMérieux) and cells were suspended in AN inoculation fluid sterile (Biolog) to a density of 0.35 and transferred to AN Microplates (Biolog) as described by the manufacturer. Incubation was carried out at 37 °C under anaerobic atmosphere for 24 h. Acid was not produced from any of the carbohydrates tested. Results for strain 7401987ᵀ are given in the species description.

Resistance to bile was verified by growing the bacteria on BYP medium supplemented with 2% (w/v) dehydrated gall salt (bile sac powder; MP Biomedicals) equivalent to 20% (v/v) bile. The strain was susceptible to bile.

Fig. 1. Transmission electron micrographs of cells of strain 7401987ᵀ. The lophotrichous flagellar arrangement is noted in the coccoid (a; bar, 200 nm) and rod (b; bar, 1 μm) forms.
Preparation and determination of cellular fatty acids were carried out by following a highly standardized method similar to the Sherlock Microbial Identification system (MIDI). The major cellular fatty acids were anteiso-C15:0 (28.2 %), C16:0 (18.0 %), iso-C15:0 (12.3 %), iso-C17:0 3-OH (11.7 %), a mixture of C18:2ω6c and anteiso-C18:0 (6.7 %), C15:0 (4.2 %), C16:0 3-OH (4.4 %), C18:0 (3.0 %), C18:1ω9c (2.5 %) and C17:0 3-OH (2.1 %).

Differential characteristics of strain 7401987ᵀ and some related taxa are shown in Table 1.

Matrix-assisted laser-desorption/ionization time-of-flight (MALDI-TOF) MS protein analysis was carried out. A smear of bacterial material was deposited on each spot of a polished-steel target plate. After air-drying, 1.5 µl matrix solution (saturated solution of α-cyanohydroxycinnamic acid in 50 % aqueous acetonitrile containing 2.5 % trifluoroacetic acid) per spot was applied. MALDI-TOF MS was conducted using the Autoflex II MS (Bruker Daltonics). All spectra were recorded in linear, positive-ion mode. The acceleration voltage was 20 kV. Spectra were collected as a sum of 675 shots across a spot. The manipulation was repeated six times. Preprocessing and identification steps were performed using the manufacturer’s parameters. Spectra were compared with the existing bank in the BIOTYPER software. No significant score was obtained, thus confirming that our isolate was not a member of a known species and, potentially, was not related to any known genus. A consensus score was obtained, thus confirming that our isolate was not a member of a known species and, potentially, was not related to any known genus. A consensus

*Porphyromonas catoniae* does not produce a black pigment on blood agar.

††, Fermentative; MF, moderately fermentative; NF, non-fermentative.

Bacterial DNA was extracted using the MagNA Pure LC DNA isolation kit III (Roche) with the MagNA Pure LC instrument as described by the manufacturer. The 16S rRNA gene of the isolated strain was amplified by PCR using the universal primer pair fD1 and rp2 (Weisburg et al., 1991). The amplified products were purified using the NucleoFast 96 PCR kit (Macherey-Nagel) according to the manufacturer’s recommendations. A BigDye Terminator cycle sequencing kit (Applied Biosystems) and ABI PRISM 3130X Genetic Analyzer (Applied Biosystems) were used for sequencing according to the manufacturer’s instructions. The different fragments were assembled using SEQUENCER software (Applied Biosystems). The sequence obtained was compared with those in GenBank by using BLAST through the NCBI server and similarities were determined. Gene sequences were aligned using the multi-sequence alignment program CLUSTAL_X version 1.8. Phylogenetic relationships with closely related species were determined using MEGA version 4 (Tamura et al., 2007). Distance matrices were determined following the assumptions described by Kimura (1980) and were used to elaborate dendrograms using the neighbour-joining method (Saitou & Nei, 1987). The maximum-parsimony algorithm was also used to infer phylogenetic relationships. A bootstrap analysis was performed to investigate the stability of the tree obtained. Bootstrap values were obtained for a consensus tree based on 100 randomly
generated trees. The tree organization was the same using the two methods (Fig. 3).

The 16S rRNA gene sequence of strain 7401987T showed similarities of 99.6, 99.8, 99.9, 99.6 and 99.6% to sequences of five previously described uncultured bacteria (GenBank accession nos AM419955, AF481203, AY005066, EF192781 and DQ633518, respectively) from noma patients, endodontic infection, subgingival plaque, dental implants and diseased distal oesophagus, respectively.

16S rRNA gene sequence comparisons revealed that strain 7401987T was distantly related to members of the genus Bacteroides (the most closely related type strain was Bacteroides vulgatus ATCC 8482T, with 83.6% similarity). All 16S rRNA gene sequences from known species from the genus Bacteroides were retrieved from GenBank. These sequences were aligned with the newly determined sequence of strain 7401987T and sequence similarity values were determined by using the program BIOEDIT (Hall, 1999). Similarities ranged from 83.6% with B. vulgatus ATCC 8482T to 68.3% with Bacteroides coagulans ATCC 29798T. Similarity values were determined between strain 7401987T and the most closely related members of the genera Porphyromonas, Prevotella, Dysgonomonas, Tannerella, Anaerophaga and Parabacteroides and are presented in Supplementary Table S1 (available in IJSEM Online).

---

**Fig. 2.** Mean spectra projection (MSP) dendrogram generated by BIOTyper software (version 2; Bruker Daltonics) showing the similarity of MALDI-TOF mass spectra of strain 7401987T and representatives of the genera Bacteroides and Prevotella.

**Fig. 3.** Phylogenetic tree showing the position of *Phocaeicola abscessus* 7401987T within the ‘Bacteroidales’. The tree was constructed by using the neighbour-joining method based on 16S rRNA gene sequences (1425 nt fragment). Numbers at nodes are proportions of 100 resamplings that support the topology shown; bootstrap values >50% are indicated. The sequence of *Bacillus cereus* ATCC 10987 was used as the outgroup. Bar, 0.05 changes per nucleotide position.
Based on phenotypic characteristics and phylogenetic analyses, a novel species in a new genus, *Phocaeicola abscessus* gen. nov., sp. nov., is proposed.

**Description of Phocaeicola gen. nov.**

*Phocaeicola* (Pho.cae.i.co’la. L. n. Phocaea a maritime town of Ionia, modern-day Foça in Turkey; L. suff. -cola inhabitant, dweller; N.L. masc. n. Phocaeicola an inhabitant of Phocaea).

Cells are Gram-negative, strictly anaerobic, non-spore-forming, motile coccobacilli with lophotrichous flagella arrangement. Catalase- and oxidase-negative. Susceptible to bile. Asaccharolytic and non-pigmented. Member of the order ‘Bacteroidales’. The type species is *Phocaeicola abscessus*.

**Description of Phocaeicola abscessus sp. nov.**

*Phocaeicola abscessus* (abs.ces’sus. L. gen. n. abscessus of an abscess).

Displays the following properties in addition to those given in the genus description. After 7 days growth in Schaedler broth, 7% cells are rods (1.7–0.4 μm wide and 1.2–6.5 μm long) and 93% cells are coc○cid (0.3–0.6 μm wide and 0.4–0.9 μm long). The optimum temperature for growth is 37 °C. After 7 days growth on chocolate agar, colonies are white, entire, circular, regular, smooth, shiny, convex and positive with API ZYM), phosphatase, leucyl glycine arylamidase and alanine dase, tyrosine arylamidase, glycine arylamidase, histidine dase, phenylalanine arylamidase, pyroglutamic arylamide and serine arylamidase. Negative reactions are obtained for alkaline phosphatase, leucyl glycine arylamidase and alanine dase, tyrosine arylamidase, glycine arylamidase, histidine dase, phenylalanine arylamidase, pyroglutamic arylamide and serine arylamidase. Using API Rapid ID 32A, positive reactions are obtained for α-glucosidase, α-glucosaminidase, mannose, N-acetyl-D-glucosamine, methyl α-D-glucoside, methyl α-xyloside, L-asparagine, glycyl-L-proline, L-methionine, L-phenylalanine, L-serine, L-threonine, L-valine, L-valine plus L-aspartic acid, 2′-deoxyadenosine, inosine, thymidine, uridine, TMP and UMP. The major cellular fatty acids are anteiso-C₁₅ : 0, C₁₆ : 0 iso-C₁₅ : 0 and iso-C₁₇ : 0 3-OH.

The type strain is 7401987T (=CCUG 55929T =CSUR P22T =DSM 21584T), isolated from a human brain abscess sample.

**Acknowledgements**

We are grateful to Bernard Campagna and Nicolas Aldrovandi for their technical assistance in electronic microscopy and to Philippe Decloquement and Carine Couderc for their assistance in mass spectrometry analysis. We are grateful to Jean Euzéby for his help in naming the bacterium.
