A novel, obligately anaerobic, psychrotolerant bacterium, designated strain PPP2T, was isolated from guano of the Magellanic penguin (Spheniscus magellanicus) in Chilean Patagonia. Cells were Gram-stain-positive, spore-forming, straight rods (0.7–0.8×3.0–5.0 μm) that were motile by means of peritrichous flagella. Growth was observed at pH 6.7–9.7 (optimum pH 8.3) and 2–37 °C (optimum 29 °C). Growth was observed between 0 and 4 % (w/v) NaCl with optimum growth at 0.5 % (w/v). Strain PPP2T was a catalase-negative chemo-organoheterotroph that was capable of fermentative metabolism. Peptone, bacto-tryptone, Casamino acids, oxalate, starch, chitin and yeast extract were utilized as substrates. The major metabolic products were acetate, butyrate and ethanol. Strain PPP2T was resistant to ampicillin, but sensitive to tetracycline, chloramphenicol, rifampicin, kanamycin, vancomycin and gentamicin. The DNA G+C content of strain PPP2T was 39.5 mol%. Phylogenetic analysis revealed that strain PPP2T was related most closely to Clostridium sticklandii SR (~90 % 16S rRNA gene sequence similarity). On the basis of phylogenetic analysis and phenotypic characteristics, strain PPP2T is considered to represent a novel species of a new genus, for which the name Proteocatella sphenisci gen. nov., sp. nov. is proposed. The type strain of Proteocatella sphenisci is PPP2T (=ATCC BAA-755T =JCM 12175T =CIP 108034T).

Microbiological investigations of penguin guano collected in Chilean Patagonia led to the isolation of two anaerobic bacterial strains capable of growth at low temperatures (Hoover et al., 2002). One of these strains, PmagG1T, was identified as a psychrotolerant, saccharolytic bacterium that was capable of growth at −5 °C, and was subsequently described as representing a novel species, Trichococcus patagoniensis (Pikuta et al., 2006). The second strain, designated PPP2T, was a Gram-positive, spore-forming proteolytic anaerobe that did not show an ability to grow at subzero temperatures (Pikuta et al., 2003; Pikuta & Hoover, 2003, 2004). Phylogenetic analysis showed that strain PPP2T was only very distantly related to any recognized species (Pikuta et al., 2003). Its closest neighbour on the phylogenetic tree, Clostridium sticklandii SR, shared only 91.3 % 16S rRNA gene sequence similarity. Phenotypically, the novel isolate was mesophilic and psychrotolerant, did not require NaCl for growth, was neutrophilic and alkalitolerant, and showed obligately anaerobic metabolism. It was a fermentative proteolytic bacterium that was able to use various products of proteolysis as substrates, but not sugars. The present article provides a detailed taxonomic description of strain PPP2T, and shows that it represents a novel species of a new genus within the family Clostridiaceae.

Strain PPP2T was isolated from a sample of guano of the Magellanic penguin (Spheniscus magellanicus) in Chilean Patagonia. Detailed descriptions of the sampling procedure and transportation to the laboratory are given in Pikuta et al. (2006).
An enrichment culture was obtained anaerobically on medium comprising (per litre): 30.0 g NaCl, 0.3 g KCl, 0.3 g KH₂PO₄, 0.1 g MgCl₂·6 H₂O, 1.0 g NH₄Cl, 0.0125 g CaSO₄·7 H₂O, 0.2 g NaHCO₃, 0.4 g Na₂S·9 H₂O, 0.001 g resazurin, 0.2 g yeast extract, 3.0 g peptone, 2 ml vitamin solution (Wolin et al., 1963) and 1 ml trace mineral solution [containing (per 500 ml): 392 mg (NH₄)₂SO₄·FeSO₄·6 H₂O, 119 mg CoCl₂·6 H₂O, 65.16 mg NiCl₂, 12.1 mg Na₂MoO₄, 16.5 mg Na₂WO₄·2 H₂O, 71.8 mg ZnSO₄·7 H₂O, 101 mg CuSO₄·5 H₂O, 43.7 mg Na₂SeO₄, 3.1 mg H₃BO₃, 49.5 mg MnCl₂·4 H₂O and 5 ml HCl]. Final pH of the medium was 7.1–7.2. High-purity nitrogen was used as the gas phase. A homogeneous sample (0.5 g) was injected into a Hungate tube, containing an anaerobic medium, and incubated for 7–10 days at 2°C. A pure culture was obtained by serial dilution in Hungate tubes and was supported on the medium described above except that the NaCl concentration was reduced to 0.5 % (w/v). The eighth dilution of a morphologically monotypic culture exhibiting growth at 2°C on peptone-containing medium was chosen for inoculation on agar medium for growth of colonies.

Isolation of colonies was performed by the roll-tube method on 3 % (w/v) agar medium. After 7–10 days cultivation on agar medium at 2°C, colonies of strain PPP2ᵀ were creamy yellow and rounded lens-shaped with a diameter of 1–2 mm. Young colonies were white. Colonies had a rough surface and central conical protuberance. Edges of the colonies were thin and smooth, and the centre of the colonies had a denser consistency and darker colour. Purification of strain PPP2ᵀ was performed at 2°C. Experiments with the pure culture were performed at 6–22°C. Purity of the culture was determined based on negative growth on D-glucose medium at room temperature and by microscope observation. The morphology of the new isolate was examined under a phase-contrast microscope (Fisher Micromaster) and FEI Tecnai 20 transmission electron microscope (FEI Co.) at 200 kV with attached digital camera. Cells of strain PPP2ᵀ were rod-shaped, with a diameter of 0.7–0.8 μm and length of 3–5 μm (Fig. 1a). Cells were motile by means of peritrichous flagella (Fig. 1b). For transmission electron microscopy, cells were concentrated by centrifugation, resuspended in 50 mM cacodylate buffer, 50 mM NaCl, pH 8.3, and then fixed with 2 % glutaraldehyde for 20 min at room temperature and negatively stained with 2 % uranyl acetate for 10–60 s.

Gram staining of cell membranes revealed a blue colour, typical of Gram-positive bacteria. Large, circular spores with a diameter twice the cell diameter were located at the centre of cells (terminal position). Cells occurred singly, in pairs or in short, irregularly curved chains. Cell division occurred by fission, sometimes unequally with the formation of terminally rounded mini-cells.

Growth was determined based on cell counts with the phase-contrast microscope or by measuring the optical density at 595 nm (Genesis 5; Spectronic Instruments). Catalase activity was determined based on the reaction with hydrogen peroxide (Gerhardt et al., 1994). All test substrates (3 g l⁻¹) were added to medium containing 0.1 g yeast extract. End products of peptone fermentation in the liquid phase were determined by HPLC. Separation was done on an Aminex HPX-87H (Bio-Rad) column with 5m MH₂SO₄ as the mobile phase. Gases were measured via a Varian 3700 gas chromatograph equipped with a Porapak Q column and thermal conductivity detector. Nitrogen was used as the carrier gas.

Strain PPP2ᵀ grew only under strictly anaerobic conditions. It was catalase-negative. Growth was observed at 0–4 % (w/v) NaCl, with optimum growth at 0.5 %; no growth occurred at 5 % NaCl. The pH range for growth was 6.7–9.7 with optimum growth at pH 8.3. The new isolate was a psychrotolerant mesophile, growing between 2 and 37°C with optimum growth at 29°C (Supplementary Fig. S1, available in IJSEM Online).

Strain PPP2ᵀ possessed a chemo-organoheterotrophic metabolism and was able to grow on the following substrates: peptone, bacto-tryptone, Casamino acids, yeast extract, starch, chitin and oxalate. Growth on starch and chitin was weak (three or four cells per field) on all three transfers for each substrate. No growth was observed on...
formate, acetate, lactate, pyruvate, propionate, butyrate, citrate, methanol, ethanol, glycerol, acetone, d-mannitol, D-glucose, D-fructose, D-ribose, trehalose, D-arabinose, maltose, D-mannose, lactose, sucrose, cellobiose, pectin, N-acetylgalactosamine, urea, trimethylamine, triethylamine or betaine. Separate amino acids on mineral medium supplemented with yeast extract (0.1 g l⁻¹) did not support growth of strain PPP₂ᵀ. No growth occurred on L-cysteine, L-cystine, L- or D-methionine, L- or D-proline, L- or D-lysine, L- or D-serine, L- or D-arginine, L-tyrosine, glycine, trans-4-hydroxy-L-proline, L- or D-histidine hydrochloride, L-glutamine, L- or D-aspartic acid, L- or D-leucine, L- or D-tryptophan, L- or D-valine, L- or D-alanine, L-glutamic acid, L-phenylalanine, L-isoleucine, L- or D-threonine or L-asparagine.

Interestingly, strain PPP₂ᵀ grew on sodium oxalate only in medium supplemented with selenium as a trace element. Cell morphology of strain PPP₂ᵀ on this substrate was atypical, with a tendency for the cells to appear swollen and with a hexagonal crystalline shape (data not shown).

The Stickland reaction was negative for the following combinations of amino acids: L-proline + L-leucine, L-proline + L-isoleucine, L-proline + L-valine, L-proline + L-alanine, glycine + L-leucine, glycine + L-isoleucine, glycine + L-valine, glycine + L-alanine and L-tryptophan + L-valine.

Two gaseous metabolic products of the culture grown on peptone-containing medium were CO₂ and H₂ (both in trace quantities, <1 %). In the liquid phase, acetate (21 mM), ethanol (4.3 mM) and butyrate (5 mM) were found.

Antibiotic resistance was tested by using the following: ampicillin, kanamycin, gentamicin, vancomycin, tetracycline, rifampicin (250 µg ml⁻¹) and chloramphenicol (125 µg ml⁻¹). Strain PPP₂ᵀ was sensitive to kanamycin, gentamicin, tetracycline, rifampicin, vancomycin and chloramphenicol, but was resistant to ampicillin.

Fatty acid methyl esters (FAMEs) were extracted from fresh biomass incubated for 4 days at 22 °C and were identified following the procedure recommended by the Microbial Identification System (MIDI Inc.) anaerobic Moore Library. The extraction procedure included sonication, methylation, organic extraction (transfer of FAMEs from an aqueous phase to an organic phase) and a base wash; cell extracts were then analysed by GC (Sherlock Microbial Identification System version 4.0; MIDI Inc.). The predominant FAMEs of strain PPP₂ᵀ were C₁₄:₀ (15.11 % of the total), C₁₆:₀ (13.97 %) and dimethyl aldehyde C₁₈:₁ cis11 (12.74 %) (Supplementary Table S1).

The G+C content of the genomic DNA of strain PPP₂ᵀ was measured by HPLC as described by Mesbah et al. (1989) except that an Alltima C18 column (250 mm × 4.6 mm, 5-μm particle size; Altech) and 8 % (v/v) methanol were used. The results reported are means ± SD of two determinations for each of two DNA degradations. The G+C content of the genomic DNA of strain PPP₂ᵀ was 39.5 ± 0.2 mol% (n=4).

Isolation of genomic DNA, amplification of the 16S rRNA gene and sequence determination were performed as described by Hoover et al. (2003). The consensus sequence was assembled by using sequence data from four different clones. The 16S rRNA gene sequence obtained was aligned with 21 similar sequences selected from a BLAST search (Altschul et al., 1990) via the GenBank database. Alignment was performed by using the CLUSTAL W program (Thompson et al., 1994). Pairwise distances were computed with MEGA version 4 (Tamura et al., 2007) by using the Jukes–Cantor model (Jukes & Cantor, 1969). An unrooted phylogenetic tree was constructed with the same program according to the neighbour-joining method (Saitou & Nei, 1987). Sites with gaps in any sequence of the alignment were excluded from all analyses.

A sequence covering 1450 nt of the 16S rRNA gene of strain PPP₂ᵀ was obtained, corresponding to positions 27–1492 of the Escherichia coli 16S rRNA gene sequence. The G+C content of this gene sequence was 53.59 mol%. A comparison with all sequences available in the GenBank database revealed over 80 % similarity with sequences from the genera Clostridium, Sporacetigenium, Eubacterium, Peptostreptococcus, Filifactor, Alkaliphilus, Geosporobacter, Acidaminobacter and Fusibacter. Although the phylogenetic dendrogram, based on 1265 common nucleotide positions (Fig. 2), showed strain PPP₂ᵀ to be related most closely to members of the genus Filifactor, highest 16S rRNA gene sequence similarity was observed with Clostridium sticklandii SR (91.3 % within the 1265 sites used for the tree and 89.4 % over a 1450-nt global alignment).

Strain PPP₂ᵀ was isolated from an alkaline sample of Magellanic penguin guano. The fact that Magellanic penguins are endemic to the southern tip of South America, a region with a very cold climate, is reflected in the physiological characteristics of strain PPP₂ᵀ: the strain showed tolerance to low temperature (down to 2 °C), high pH and marine concentrations of NaCl. All these environmental factors have had an influence on the phenotype of strain PPP₂ᵀ, probably as a result of the adaptive flexibility of its genome. The ability of the new isolate to use exclusively products of proteolysis and oxalate (but not sugars) is probably due to the restricted diet of these penguins: they feed on marine fish and crustaceans.

It is of note that strain PPP₂ᵀ is resistant to ampicillin, a characteristic that is extremely rare in environmental bacterial strains. The closest phylogenetic neighbour to strain PPP₂ᵀ based on 16S rRNA gene sequences was C. sticklandii SR, but with ~10 % sequence divergence, and therefore phenotypic comparisons with other recognized species were unnecessary. Strain PPP₂ᵀ showed phenotypic features typical of the family Clostridiales: strictly anaerobic growth, spore formation, Gram-positive cell walls, fermentative metabolism and acetogenesis. Table 1 shows distinguishing features between strain PPP₂ᵀ and recognized mesophilic, anaerobic, acetogenic genera of the family Clostridiales.
Based on its phenotypic and genotypic characteristics (Gram-positive cell wall, spore formation, obligately anaerobic and fermentative metabolism, mesophilic/psychrotolerant and neutrophilic/alkalitolerant physiology, no NaCl requirement for growth, fatty acid profile and 16S rRNA gene sequence), strain PPP2T is considered to represent a novel species of a new genus, for which the name *Proteocatella sphenisci* gen. nov., sp. nov. is proposed.

**Description of Proteocatella gen. nov.**

*Proteocatella* (Pro’te.o.ca.tel’la. N.L. n. proteinum protein; N.L. pref. proteo- prefix referring to protein used in compound words; L. fem. n. catella small chain; N.L. fem. n. Proteocatella a small chain using proteins).

*AN (ATL), Aerotolerant anaerobe; OAN, obligate anaerobe.
†Oligospore-forming.
§K. Takai, personal communication.
Do not require carbonate ions or NaCl for growth. Psychrotolerant mesophiles. Acetogenic (producing acetate as major end product). The type species is *Proteocatella sphenisci*.

**Description of Proteocatella sphenisci** sp. nov.

*Proteocatella sphenisci* (sphe. n(is) ci. N.L. gen. n. sphenisci of *Spheniscus*, zoological name of a genus of penguin, referring to the isolation of the type strain from guano of *Spheniscus magellanicus*, the Magellanic penguin).

Has the following characteristics in addition to those given for the genus above. Cells are flexible, motile rods, 0.7–0.8 × 3.0–5.0 μm, that tend to form long chains. Multiplying by fission, sometimes unequally with the formation of terminally round mini-cells. Motile by means of flagella. Spores are spherical. Sporangium is not swollen. Grows at 2–37 °C (optimum 29 °C) and at pH 6.7–9.7 (at 22 °C) (optimum pH 8.3). NaCl range for growth is 0–4% (w/v); optimal growth at 0.5% (w/v) NaCl. Catalase-negative. Heterotrophic growth with peptone, bacto-tryptone, Casamino acids, oxalate, starch, chitin and yeast extract. End products of peptone fermentation are acetate, butyrate and ethanol and, in the gas phase, minor products are hydrogen and carbon dioxide. Resistant to ampicillin, but sensitive to kanamycin, gentamicin, tetracycline, rifampicin, vancomycin and chloramphenicol. The G + C content of the genomic DNA of the type strain is 39.5 mol% (HPLC).

The type strain, PPP2T (=ATCC BAA-755T =JCM 12175T =CIP 108034T), was isolated from guano of Magellanic penguins (*Spheniscus magellanicus*) inhabiting the coast of Chilean Patagonia.

**Acknowledgements**

We are grateful to Dr Vadim V. Kevbrin and Professor J. Wiegel (University of Georgia, Athens) for assistance in measuring end products, and for access to phase-contrast microscopy. We wish to acknowledge the NASA JSC Astrobiology Institute for Biomarkers in Astromaterials for financial support.
