PLATES XXXII–XXXIV

The first detailed description of the appearance of *Vibrio fetus* in stained smears was given by Smith and Taylor (1919). More recently, the electron microscope has been used for the study of shadow-cast preparations (Rhoades, 1954) and ultrathin sections (Werner, Levy and Spurlock, 1961; Werner, 1963). Studies by several techniques were described by Ritchie, Keeler and Bryner (1966). After the description of microaerophilic vibrios in association with human gastroenteritis (Vinzent, Dumas and Picard, 1947), the organism has been reclassified as a *Campylobacter* (Vérón and Chatelain, 1973; Smibert, 1974). Strains of *Campylobacter jejuni* isolated from patients with gastroenteritis differ from animal strains of *V. fetus* in possessing a higher optimum growth temperature, 43°C, and bile tolerance. More recently, selective techniques (Butzler et al., 1973; Skirrow, 1977) have enabled diagnostic laboratories to attempt routine isolation of the organism. This report describes morphological findings from the electronmicroscopic study of some strains of *C. jejuni* isolated from human patients.

MATERIALS AND METHODS

Isolation and identification of organisms. Liquid stools from 56 patients with acute gastroenteritis were cultured by the selective method described by Skirrow (1977). Colonies were subcultured on MacConkey agar, nutrient agar enriched with horse blood 10% (v/v), and salt broth. Isolates were provisionally identified by gram-staining reaction, motility, oxidase reaction, catalase production and antibiotic-sensitivity pattern. Confirmatory tests included H₂S production, 2, 3, 5-triphenyltetrazolium chloride tolerance, sensitivity to metronidazole and inhibition by nalidixic acid.

Electronmicroscopy. Organisms were removed from culture media and emulsified in phosphate-buffered saline (Oxoid). A small quantity of the suspension was diluted in distilled water containing a trace of bovine serum albumin and was then mixed with an aqueous solution of potassium phosphotungstate 1% (w/v) at pH 6.5. This negatively stained preparation was applied to a formvar-carbon grid of 400 mesh and examined in an AEI Corinth 500 electron microscope. In addition, some cultures were examined after prolonged incubation.

RESULTS

There were five isolations of *C. jejuni* from the 56 stools. Morphologically, all strains were very similar. In the negatively stained preparations most cells were S-shaped or elongated spirals (fig. 1), resembling some *Spirillum* spp., and were 1.4–3.0 μm long and 0.4–0.6 μm wide. A few comma-shaped organisms were seen. Some paired organisms were seen in tandem, presumably undergoing division, but longer chains of organisms were not observed. Round "coccoidal" forms 0.6–1.2 μm in diameter were also seen (fig. 2).

Numerous globular extrusions of the cell wall (fig. 3) were seen in preparations of each form of the organism. The cytoplasmic membrane was slightly uneven in outline but did not display extrusions, and in most cases was smoothly contoured, forming the basic shape of the organism.
(fig. 3). This membrane appeared to be convoluted in some organisms, probably due to retraction within the cell wall (fig. 4). The cytoplasm was seen as a compact matrix and in some organisms the only discernable feature was the mottled surface effect of the cytoplasmic contents. Occasionally the cytoplasm was seen to be traversed by dark-staining clefts (fig. 4). Disc-shaped electron-dense inclusions measuring 95–155 nm were seen in some of the S-shaped organisms (fig. 4).

Most organisms possessed bipolar flagella; some had a single polar flagellum but non-flagellate forms were rarely seen. The flagellar length ranged from 2.6 to 3.9 μm and the diameter averaged 21 nm. A parallel linear substructure was visible, but a flagellar sheath was not evident (fig. 5). The site of flagellar attachment to the organisms was usually within a concave depression (fig. 6). Frequently, a prominent electron-lucid rim was visible at the periphery of the depression. Closer examination of the site of attachment in partially autolysed organisms showed the flagellum fastened to thickened areas of the cell wall and cytoplasmic membrane.

Prolonged incubation of the cultures resulted in an increase in the number of coccoidal forms; after incubation for 72 h, at least 50% of the observed bacterial population consisted of coccoidal forms.

**DISCUSSION**

Examination of the five strains of *C. jejuni* isolated from humans demonstrated a close morphological similarity to *V. fetus* of veterinary origin as described by Ritchie et al. (1966). These authors also observed cell-wall extrusions, cytoplasmic clefts and electron-dense intracytoplasmic inclusions in sectioned and unfixed whole-cell preparations. Electron-dense inclusions have also been reported by others (Werner et al., 1961; Werner, 1963) in sectioned organisms. No large terminal bodies or lamellar bodies as described by Ritchie et al. (1966) were seen in the present study. Most of the cells in the preparations possessed bipolar flagella. Some accounts have reported a unipolar distribution in *V. fetus* as more common (Smith and Taylor, 1919; Rhoades, 1954; Véron and Chatelain, 1973). Flagellar size and ultrastructure noted in the present study closely resembled that of *C. fetus* described by McCoy et al. (1975). The mode of flagellar attachment in *C. jejuni* was very similar to that demonstrated in vibrios by Vaituzis and Doetsch (1969). The increase in coccoidal morphology during prolonged incubation is presumed to be associated with a decrease of available nutrient.

**SUMMARY**

Stools from 56 patients with gastroenteritis were cultured for *Campylobacter jejuni*. The five strains isolated were examined by electron microscopy. The campylobacter cells were pleomorphic and most displayed appearances similar to those of *V. fetus*. Morphological changes were observed in cultures subjected to prolonged incubation.

I would like to thank Dr S. A. Rousseau and Dr A. K. Chaudhuri for supplying cultures and Dr A. A. Saeed and Miss S. I. Hayter for their help in the preparation of the manuscript.
