reproduction (which includes even typist’s errors and corrections), style, nomenclature, spelling and abbreviations, some of which are indeed rather curious if not unconventional. The irritation of the reader will also be compounded by the fact that 2 years have elapsed since this interesting, informative and valuable symposium was held, and, at £21.75, the price is little short of outrageous even in these days of high inflation. It is difficult to apportion the blame between the senior editor and the publisher, but it is most unfortunate that greater attention was not devoted to making this report on an important topical subject available to the medical and scientific community before the proceedings of the symposium were overtaken by rapid progress.

A. J. ZUCKERMAN

**Microbiology for clinicians**

In the foreword to this little book, Dr Grüneberg identifies the clinician’s two microbiological needs as a smattering of general information and a knowledge of where to turn for the detail that is occasionally necessary for the management of a particular patient. The latter is relatively straightforward; the former is not, and the author is to be commended in his attempt to meet it. The likelihood of success must hinge in part on the difference between need as perceived, on the one hand by a microbiologist and, on the other, by the clinician himself. I suspect that few would wish to spare the time to study the simple framework that Dr Grüneberg has provided. Given that I am wrong, how adequate is the framework? On the face of it, the book covers most aspects of the interrelationship between microbiologist and clinician, but in the search for simplicity much has been sacrificed. Many of the earlier chapters are more suited to the medical student or even to the interested sixth-former, with the pursuit of the non-technical resulting in an appearance of condescension over a more senior reader. Parenthetic notes of the kind “... *Neisseria gonorrhoeae* (the causative agent of gonorrhoea). . .” and “... german measles (rubella)”, illustrate this. Surely we must assume that a doctor does not emerge from medical school entirely unaffected by teaching in microbiology. Add the recurring theme of University College Hospital practice and the doings of great UCH men, and the, to me, annoying quotations to complete the conviction that this text has a domestic undergraduate origin.

Yet, there are many good things. I well remember a senior clinician responding to my report of an outbreak among his patients, with the remark that I had been given something interesting to do. Dr Grüneberg conveys at least something of the contrary view that most of what we do is interesting, and that there is much that the clinician can do to make it more so. Perhaps again Dr Grüneberg’s personal views are sometimes over-emphasised. I hope that we shall not be considered negligent if we decline to monitor serum gentamicin levels in all patients treated for more than 48 hours, and that prophylactic metronidazole will not be abandoned for povidone iodine on the strength of his opinions, for example.

I fear that although the aims of the book were admirable the target will remain blissfully unaware or, if aware, largely content in its ignorance.

I. PHILLIPS

**Adhesion and microorganism pathogenicity**

This volume is primarily concerned with the adhesion of micro-organisms to eukaryotic cells. Carbohydrates provide the chemical basis for many of the eukaryotic cell receptors. The reciprocal structure on the micro-organism, the adhesin (often associated with pili and fimbriae), appears in many instances to have the characteristics of lectin molecules.

The participants bring together information on a wide range of adherence phenomena, from the well known *E. coli* mannose-specific binding interactions to the binding of *Entamoeba*
