**Summary.** A range of solid and liquid media was evaluated for the ability to maintain survival of *Helicobacter pylori* strains under different conditions. Chocolate agar slopes maintained survival of most strains for longer than 3 days, some strains surviving for up to 9 days, despite a decreased number of viable cells. Temperature and atmosphere did not significantly influence the performance of these slopes. The BBL Campy Pouch system also achieved a considerable recovery rate of *H. pylori* after storage for 3 days at the same range of temperatures. Brain-heart infusion broth with horse serum was superior among the liquid media tested, maintaining the viability of *H. pylori* for c. 3 days at temperatures ranging from -4°C to 21°C. Chocolate agar slopes are recommended as suitable for transport of *H. pylori* strains.

**Introduction**

Since the first successful isolation of *Helicobacter pylori* from gastric mucosa in 1983,1 techniques and media for isolating, subculturing and storing this organism have been well established.2-5 Methods for growing *H. pylori* in various liquid media have also been evaluated.5-8 *H. pylori* is a fastidious, micro-aerophilic species that can survive at temperatures from 4°C to room temperature (21°C) for only 5-48 h in most conventional media such as nutrient broth,9 thiglycollate broth,10 Brucella broth, normal saline,11 hypertonic glucose12 and Stuart’s transport medium.13 Therefore, transportation of this organism is difficult and recovery from freeze-dried cultures is poor.12

The aim of this study was to determine the survival time of *H. pylori* cultures in a number of potential transport media, and particularly on chocolate agar slopes, at different temperatures, with and without the addition of CO₂ to the atmosphere.

**Materials and methods**

**Bacterial strains**

All *H. pylori* strains in the present study were isolated from antral biopsy specimens, and were identified by their typical morphology with Gram’s stain, rapid urease reaction and positive oxidase and catalase tests. Sixteen strains were used to evaluate solid media, four for atmospheric requirements for chocolate agar slopes and 16 for BBL Campy Pouch evaluation. Twelve strains were used to study liquid media.

**Evaluation of solid media**

Chocolate agar plates (CAP) and chocolate agar slopes (CAS) were prepared from Columbia Agar Base (Lab M, Bury) with heated horse blood 7%. Three-day-old cultures of 16 strains from CAP were subcultured on to CAP and CAS. These were then incubated at 37°C for 3 days and were then held at room temperature (21°C) and external environmental temperature (i.e., outside at winter temperatures ranging from -4°C to 14°C). Subcultures to CAP were carried out at 3 h and 1, 2, 3, 5, 7, 9 and 11 days to check the viability of the strains.

To evaluate the capability of BBL Campy Pouches (Cam.P; BBL Microbiology Systems, Cockeysville, MD, USA) to maintain viability of *H. pylori*, the strains were inoculated on to CAP and incubated at 37°C for 3 days. The plates were sealed in the Campy Pouches according to the manufacturer’s instructions and held at the same range of temperatures. Subcultures were performed at the same time intervals as before.

All subcultures were placed in Gaspak jars (Gaspak System, BBL), flushed with CO₂, and incubated at 37°C for 5-7 days. Growth of colonies was scored according to density as +++, ++, +, and negative (−).
Determination of transport conditions for CAS

As CAS gave the best results in the previous experiments, it was decided to determine the effect of atmospheric conditions on their performance. Four *H. pylori* strains (IRL911200, IRL911201, IRL911206 and IRL911207) were each subcultured on six CAS and incubated for 4 days. Each set of six was divided into three pairs, CO₂ was added to one of each pair and the pairs were then stored at 37°C, room temperature and external environmental temperature as before. The slopes were subcultured at 3 h, 2, 4, 6, 8 and 10 days, as described previously.

Evaluation of liquid media

The three liquid media tested were Nutrient Broth No. 2 (NB, Oxoid), Brain Heart Infusion Broth (Oxoid) with horse serum (Oxoid) 10% (BHIS), Tryptone Soya Broth (Oxoid) with glycerol (BDH, Laboratory Supplies, Poole) 30% and horse serum 10% (TSGS). These liquid media were assessed as transport media. Because it is difficult to grow the organism in liquid culture, 3-day-old subcultures of 12 strains from CAP were suspended in 5 ml of the broths, yielding a density of c. 10⁷ cfu/ml. These suspensions were placed directly at the room temperature and the external environmental temperature. Subcultures were performed at 3 h and 1, 2, 3, 5, 7, 9 and 11 days, as previously described.

Results

Evaluation of solid media

The survival time of *H. pylori* on CAS was much longer than on CAP. However, CAP in the BBL Campy Pouch system gave a similar recovery rate to CAS within 3 days of storage, but could not maintain viable *H. pylori* for 9 days (fig. 1).

Determination of transport conditions for CAS

All four strains survived on CAS for at least 2 days at different temperatures and two strains survived for

*See footnote to table I.
up to 8 days at 37°C. Incubation with CO₂ or exposure to air did not significantly influence recovery rate. The recovery rates at 37°C seemed to be higher than those at external temperature or room temperature (tables I and II).

**Evaluation of liquid transport media**

The survival time of *H. pylori* in BHIS was longer than in the other two liquid media tested. The recovery rate varied between 80 and 90% after storage for 3 days in BHIS, 50% in NB and zero in TSGS (fig. 2). The recovery rate of *H. pylori* after storage at external temperature (−4°C to 14°C) was higher than that at room temperature (21°C) in all media (figs. 1 and 2).

**Discussion**

The availability of a suitable transport medium would greatly facilitate the transport of *H. pylori* cultures to different laboratories for study. However, no suitable transport system has been developed so far. In the present study, brain-heart infusion with horse serum 10% maintained viability of most *H. pylori* strains for longer than 3 days at temperatures from −4°C to 21°C, which shows that this medium would be suitable for transporting or mailing *H. pylori* strains. Only half of the strains in this study survived for 3 days at ambient temperatures in nutrient broth, which is used frequently to transport gastric biopsy specimens for isolation of *H. pylori*. Addition of horse serum may increase the recovery rate. Tryptone soy broth with glycerol 30% and horse serum 10% has been used as a storage medium in our laboratory and maintains the viability of *H. pylori* for > 18 months at −70°C (unpublished observation). None of the strains in this study survived in this medium at −4°C to 21°C for > 1 day.

However, broths are easily contaminated and less convenient to use than solid media. Most *H. pylori* strains did not survive on CAP after storage for 1 day at −4°C to 21°C. However, CAS maintained viability of all the *H. pylori* strains for 3 days and some strains for 9 days. The BBL Campy Pouch system also allowed a high recovery rate of *H. pylori* strains from CAP, but the expense and cumbersome nature of the system detracted from its value.

CO₂ is essential for the isolation of *H. pylori* from gastric biopsy specimens. However, once isolated, most strains were capable of growth in an atmosphere with high humidity but without the addition of CO₂ (unpublished observation). In the present study, the addition of CO₂ had little effect on the recovery rate of *H. pylori*, which suggests that CO₂ is not important for the maintenance of viable *H. pylori* in transport media.

Temperature can influence the recovery rate of *H. pylori*. In the present study, a higher recovery rate was achieved when the cultures were stored at −4°C to 14°C than that at 21°C. For CAS, storage at 37°C with or without the addition of CO₂ prolonged the survival time of *H. pylori*. However, CAS at ambient temperature is a convenient medium for the effective transport of *H. pylori*.

Thus, although brain heart infusion with horse serum 10%, the BBL Campy Pouch and CAS can maintain survival of most *H. pylori* strains for longer than 3 days at ambient temperature, we consider CAS with or without the addition of CO₂ to be the most suitable transport system at present.

We thank Mr L. English and Dr F. Falkiner of the Department of Clinical Microbiology, St James’s Hospital, Dublin, for their technical advice and for reading the manuscript.
