BACTERIAL PATHOGENICITY

Production and characterisation of monoclonal antibodies to heat-shock protein 60 of Helicobacter pylori

Two monoclonal antibodies (MAbs), designated as H9 (IgG2a) and H20 (IgM), directed against heat-shock protein 60 (HSP60) of Helicobacter pylori strain TK1029 were established. Affinity-purified antigens cross-reacted in immunoblots with MAb H9 and MAb H20 respectively. These antigens also reacted with the 3C8 MAb previously established in this laboratory, which recognised Yersinia enterocolitica HSP60. By amino-acid sequence analysis, the N-terminal amino-acid sequence of the protein recognised by both H9 and H20 MAbs was confirmed as the amino-acid sequence of H. pylori HSP60 reported previously. Both MAbs reacted with nine strains of H. pylori in enzyme-linked immunosorbent assay (ELISA) and immunoblot analysis. In addition, MAb H9 reacted with extracts of other bacteria including H. mustelae, Pseudomonas aeruginosa, Vibrio cholerae, Serratia marcescens, Proteus mirabilis, Escherichia coli and Shigella sonnei. In contrast, MAb H20 reacted only with strains H. pylori. These results suggest that both the species-specific epitope recognised by MAb H20 and the common epitope recognised by MAb H9 exist on HSP60 of the bacterial cell. Both MAbs also reacted with the 60-kDa protein in the lysate of human gastric carcinoma (MKN45) cells. It was shown by immunohistochemical staining that gastric epithelial cells of four out of six biopsy specimens examined stained positively with MAb H20. These results suggest that there is a common epitope in H. pylori HSP60 and human gastric epithelial cells.

Introduction

Helicobacter pylori is a gram-negative, spiral-shaped bacterium that colonises human gastric mucosa and is implicated in the causation of peptic ulcer disease, gastric carcinoma and gastric lymphoma [1–3]. Various virulence factors have been identified in H. pylori including flagella [4, 5], adhesin [6], urease [7, 8], vacuolating toxin [9, 10] and the toxin that inhibits secretion of gastric acid in vitro [11, 12]. However, the pathogenic mechanism by which H. pylori persists in the stomach is not fully understood.

Heat-shock proteins (HSPs) are highly conserved proteins found in all prokaryotic and eukaryotic cells, induced by environmental stress including temperature chain, inflammation, viral infection and malignant transformation [13–15]. The HSP60 family of chaperonins such as GroEL of Escherichia coli and the 65-kDa immunodominant antigen of Mycobacterium spp. is thought to facilitate folding, unfolding and translocation of polypeptides, as well as the assembly and fragmentation of oligomeric protein complexes [16–18]. H. pylori HSP60 has been reported to be associated with urease [19, 20]. A recent study demonstrated a correlation between the adhesion of H. pylori to human gastric carcinoma cells and expression of HSP60 on the cell surface [21]. The results suggested that the adhesion of H. pylori to human gastric cells might be associated with the HSP60, and also indicated a potential role of HSP60 as one of the virulence factors responsible for the induction of gastritis. However, the immunological nature of H. pylori HSP60 is currently unknown.

On the other hand, several investigators reported that H. pylori induces autoantibodies that play a crucial role in the pathogenesis of gastritis and gastric atrophy [22, 23]. Autoimmunity also might play a role in the pathogenesis of H. pylori-linked chronic gastritis and carcinoma [2, 3]. To understand the autoimmune...
response involved in induction of chronic gastritis and carcinoma by *H. pylori*, studies of epitope homology between HSP60 of *H. pylori* and human gastric epithelial cells must be important.

The present study established monoclonal antibodies (MAbs), designated as H9 and H20, directed against HSP60 of *H. pylori* and studied the immunological characteristics of epitopes of HSP60 with an enzyme-linked immunosorbent assay (ELISA) and immunoblotting with the MAbs. It also investigated cross-reactivities between *H. pylori* and human gastric cells with these MAbs.

**Materials and methods**

**Bacterial strains and culture conditions**

*H. pylori* TK strains used in this study were isolated from gastric biopsy samples of patients as described previously [24]. *H. pylori* NCTC11638 and *H. mustelae* NCTC12032 were kindly provided by Dr T. Ito (Tokyo Metropolitan Research Laboratory of Public Health). These bacteria were cultured in Brain Heart Infusion (BHI) agar (Difco Laboratories, Detroit, USA) with defibrinated horse blood (BHI-blood plate) 5% in an atmosphere consisting of O2 5%, CO2 10%, N2 85% for 4 days at 37°C. *Pseudomonas aeruginosa*, *Vibrio cholerae*, *Serratia marcescens*, *Proteus mirabilis*, *E. coli* and *Shigella sonnei* were obtained from the strain collection of the Department of Microbiology, Kyorin University School of Medicine. Cultures were harvested and then washed with phosphate-buffered saline (PBS); 0.14 M NaCl in 20 mM sodium phosphate buffer, pH 7.4. The cells were resuspended in PBS and treated with an ultrasonic disintegrator UR-200P (Tomy Seiko Co., Tokyo, Japan) for 1 min at 20 kHz. The sonicated antigens were used for the ELISA and SDS-PAGE.

**Cell culture**

The human gastric carcinoma (MKN45) cell line was obtained from the Japanese Cancer Research Resources Bank (JCRB). MKN45 cells were grown at 37°C in RPMI1640 (Gibco Laboratories, NY, USA) containing fetal calf serum (FCS; Wako Pure Chemical Ltd, Osaka, Japan) 10% in an atmosphere of air with CO2 5%. The cells were resuspended in PBS and ultrasonically disintegrated as described above. The sonicated cells were used for ELISA and SDS-PAGE.

**Preparation of monoclonal antibodies**

MAb was prepared by the method described previously [25]. The 60-kDa antigen derived from *H. pylori* TK1029, partially purified by extraction from the separation gel by SDS-PAGE. BALB/c mice were immunised intraperitoneally (i.p.) with the antigen mixed with Freund’s complete adjuvant (Difco Laboratories), three times at intervals of 10 days. Ten days after the last i.p. injection, the mice were given the partially purified antigen by intravenous injection. Three days later the spleen was removed for cell fusion of spleen cells and mouse myeloma cells (P3-X63-Ag8-U1). The hybridoma cells producing MAb which reacted with the partially purified antigen, purified HSP60 from *Yersinia enterocolitica* [26] and the sonicated MKN45 cells were collected. The hybridoma cells displaying apparent specific antibody production were cloned by limiting dilution and 106 cells were inoculated i.p. into BALB/c mice pretreated i.p. with pristane (Wako Pure Chemical Co. Ltd) 0.5 ml 4 days before injection of the cells. Approximately 2 weeks later, ascites fluids were obtained from each mouse. The immunoglobulins in the ascites fluids were purified with an Immunoglobulin-Easy-Separation kit (Pharmacia Biotech. Co., Tokyo, Japan). The purified MAbs were used for ELISA, immunoblotting, flow cytometric analysis, immunohistochemical staining and affinity purification of the antigen recognised by the MAbs.

**Microsequencing of protein**

To analyse the N-terminal protein sequence, the whole proteins of *H. pylori* TK1029 were separated by SDS-PAGE and transferred onto Immobilon membranes (Millipore, Bedford, USA). The band corresponding to the protein which recognised the H9 and H20 MAbs was excised from the membrane. The membrane piece was sequenced by a protein sequencer (473A; Applied Biosystems, Foster City, USA).

**ELISA**

ELISA was performed as previously reported [27]; 96-well microtitration plates were coated for 2 h with partially purified 60-kDa antigen derived from *H. pylori* TK1029, *Y. enterocolitica* HSP60 and the sonicated antigens from MKN45 cells at a concentration of 1 μg/well. After washing with PBS, the plates were incubated with skimmed milk (Yukijirushi Nyugyo Co., Tokyo, Japan) 1% w/v (PBS-S) for 1 h at room temperature. The plates were then incubated for 1 h at room temperature with MAbs H9 and H20, diluted to 1 μg/ml with PBS-S. After washing, the plates were incubated with goat anti-mouse IgG and IgM peroxidase conjugate (Caperl Research Products, Durham, USA) diluted 1 in 500 with PBS-S. Then the plates were developed with OPD buffer (0.1 M citric acid, 0.07 M sodium phosphate 12-hydrate and H2O2 0.015% w/v containing o-phenylenediamine 0.1% w/v. After 5 min for the reaction, the colour which developed was measured at 490 nm.

**SDS-PAGE and immunoblotting**

SDS-PAGE was done with acrylamide 10% w/v as described by Laemmli [28]. Bacterial cells were
harvested and resuspended in 100 μl of the lysis buffer (0.4 mM 2-mercaptoethanol, Nonidet P-40 3.2% v/v, lysed by seven freeze-thaw cycles (frozen at −80°C and thawed at 37°C in a water-bath, each for 5 min). Cell lysates (100 μl) were heated for 5 min at 100°C in sample buffer (0.00625 M Tris-HCl, pH 6.8, containing SDS 2% w/v, glycerol 5% v/v and 2-mercaptoethanol 5% v/v). Finally, 10 μl of the cell lysates were loaded per lane. Immunoblot analysis was as described by Towbin et al. [29]. After electrophoresis, the separated proteins were transferred to nitrocellulose membranes (Schleicher and Schuell, Dassel, Germany) at 0.25 A overnight. After blocking with gelatin 3% w/v in Tris-buffered saline (0.15 M NaCl, 10 mM Tris-HCl, pH 7.4), the membranes were treated for 1 h with MAbs H9 or MAb H20 diluted to 1 μg/ml with the blocking buffer. Then, they were incubated for 1 h with goat anti-mouse IgG and IgM peroxidase conjugate (Capel Research Products) diluted 1 in 500 with Tris-buffered saline containing bovine serum albumin (BSA) 1% w/v. Immunoblots were developed with Tris-saline containing H2O2 0.12% v/v and 1 mM o-dianisidine.

Immunohistochemical staining of gastric biopsy specimens with MAbs H9 or MAb H20 to bacterial HSP60

Frozen sections 4 μm thickness obtained from six separate biopsy specimens were placed on glass slides. They were fixed in acetone for 5 min at 4°C, followed by washing with distilled water. Endogenous peroxidase was blocked by incubation with H2O2 0.1% v/v for 10 min at room temperature. After washing with PBS containing Tween 20 (Wako Pure Chemical Ltd) 0.2% v/v (washing buffer), the sections were allowed to react with normal horse serum diluted 1 in 10 with PBS-S for 30 min to reduce non-specific staining. The sections were then treated overnight at 4°C with either MAbs H9 or MAb H20 (1 μg/ml) diluted with PBS-S or control mouse MAb (IgG or M) recognising glucose oxidase derived from Aspergillus niger (Dako Japan Co. Ltd, Kyoto, Japan). After the sections were treated with the washing buffer they were incubated with biotinylated anti-mouse IgG or IgM secondary antibody (Dako Japan Co. Ltd) diluted 1 in 100 with PBS-S. Development by the peroxidase method with avidin-biotinylated enzyme complex and 3,3′-diaminobenzidine, tetrahydrochloride was performed with the vectastain ABC kit (Funakoshi Co. Ltd, Tokyo, Japan).

Results

Cross-reaction between the affinity-purified antigens and MAbs H9 or MAb H20

The study determined whether the molecule recognised by MAbs H9 corresponded to that directed to MAb H20. The molecules recognised with the MAbs were purified by affinity chromatography with MAbs H9 or H20. The purified antigens cross-reacted with MAbs H9 and H20 (Fig. 1a and b). The purified antigen also reacted with MAb 3C8 raised against Y. enterocolitica HSP60 as previously established (Fig. 1c) [25 30]. The N-terminal amino-acid sequences of the 60-kDa proteins recognised by both MAbs were as follows: "****IKFSVYAMKLLFEGV∗" (∗ denotes unsuccessful determination, and the underlined sequence shows an identical correspondence to H. pylori HSP60 reported previously [31, 32]. These results indicate that the molecule recognised by both MAbs is a homologue of H. pylori HSP60.

Reactivities of various bacteria and MKN45 cells with MAbs H9 and H20

Table 1 shows the reactivities of MAbs H9 and H20, in both ELISA and by immunoblotting against sonicated crude antigens of nine strains of H. pylori and seven other bacterial species including H. mustelae, P. aeruginosa, S. marcescens, Pr. mirabilis, E. coli and S. sonnei. MAb H9 displayed broad reactivity in ELISA, recognising all the bacterial antigens used in the present study. On the other hand, MAb H20 recognised only the antigen from strains of H. pylori, indicating that this MAb reacted with a species-specific epitope. Similarly, it was demonstrated in immunoblotting that MAb H9 reacted with 60-kDa antigens of all bacteria and MAb H20 recognised only the 60-kDa antigen of strains of H. pylori. Both MAbs reacted with the 60-kDa band in sonicated cell antigens of MKN45 by immunoblot analysis (Fig. 2).

* +, detection of reacting protein band of 60-kDa by immunoblotting; –, denotes no detection of reacting band in the size by immunoblotting.
* Reactivities were measured by ELISA and immunoblot analysis.
* Value of OD490 measured by ELISA.

Reactivities of gastric biopsy specimens with MAbs H9 and H20 by immunohistochemical staining

Immunohistochemical staining of six gastric biopsy specimens from patients with gastritis was performed with MAbs H9 and H20 directed against *H. pylori* HSP60 (Fig. 3). All gastric biopsy samples were positive for both the rapid urease test and the isolation of *H. pylori*. Gastric epithelial cells of four biopsy samples stained positively with MAb H20 (Fig. 3A, C, D and F) but the other two biopsy specimens were not stained with MAb H20 (Fig. 3B and E). On the other hand, no gastric biopsy specimens reacted with either MAb H9 or negative control MAbs (both immunoglobulin G and M) directed against the glucose oxidase derived from *Aspergillus niger* (data not shown).

Discussion

The present study established two MAbs, designated as H9 and H20, against *H. pylori* HSP60 and described the characteristics of the epitopes recognised by these MAbs. The epitope recognised by MAb H9 is similar to the common epitope recognised by MAb 3C8 as reported previously [25, 30], as MAb H9 reacted with the 60-kDa protein of all bacteria used in the present study and MKN45 cells. In contrast, MAb H20 recognised the species-specific epitope on *H. pylori* HSP60 and the epitope was also shown to exist on a 60-kDa molecule of human gastric carcinoma MKN45 cells. It has already been reported that MAb H20 inhibited adhesion of *H. pylori* to human gastric epithelial cells, indicating that the HSP60 epitope recognised by MAb H20 might be important in the adhesion of *H. pylori* [32]. The results indicated that a species-specific epitope exists on *H. pylori* HSP60 and there was epitope homology between *H. pylori* HSP60 and human gastric cells.

Immunohistochemical staining demonstrated that MAb H20 reacted with four of six gastric biopsy specimens obtained from patients with gastritis. In contrast, MAb H9 reacted with no gastric biopsy specimens at all. However, both MAbs reacted with the 60-kDa molecule of human gastric carcinoma MKN45 cells in immunoblotting. These results indicated that the epitope recognised with MAb H20 was *H. pylori*-specific and expressed on gastric epithelial cells as well as *H. pylori*, and that the amount of the expressed epitope differed among different gastric biopsy specimens. It also indicated that MAb H9 reacting epitope is universally detected on a broad range of bacterial species.
spectrum of bacteria but was not detected on primary gastric epithelial cells.

An autoimmune reaction in gastroduodenal diseases might play an important role in the pathogenicity of *H. pylori* [23, 33]. However, the *H. pylori* antigens that induce an autoimmune reaction are currently unknown. Appelmelk *et al.* [34] reported a potential role of molecular mimicry between *H. pylori* lipopolysaccharide and host Lewis blood group antigens in autoimmunity. Macchia *et al.* [31] suggested that a role for *H. pylori* HSP60 in induction of gastritis by autoimmunity might be important.

The role of HSPs in the pathogenesis of various diseases has been suggested in various clinical syndromes and bacterial infections [14, 35–37]. It was also reported that *H. pylori* induces an immune response against its HSP60 in c. 50% of patients infected by the bacterium and that sera from uninfected people do not recognise this protein [31]. The present study demonstrated an epitope homology between *H. pylori* HSP60 and human gastric epithelial cells. The results suggest that the recognition of its HSP60 in infection with *H. pylori* could induce an autoimmune reaction against gastric epithelial cells. HSP60 proteins are the most conserved proteins among all living organisms, not only in prokaryotic but also in eukaryotic cells [17, 18]. The homology between the amino-acid sequences of these molecules is very high, indicating that a common epitope exists on HSP60. However, an intense immune response against the common epitope of *H. pylori* might not be important for the induction of autoimmunity, as such an immune response should be eliminated by tolerance [31].

Therefore, we speculate that the specific epitope on *H. pylori* HSP60, like the epitope recognised with MAb H20, and capable of cross-reacting with human gastric cells, could induce an autoimmune response against human gastric epithelial cells.

This study was supported in part by a grant for scientific research from the Ministry of Education, Science, Sport and Culture of Japan.
