(Received 7 February 1983; revised 14 June 1983)

*Rhizobium* strain BTAi 1 which was isolated from a stem nodule on *Aeschynomene indica* was a fast grower with mean generation times of 3.2 and 4.0 h with glucose and mannitol, respectively. Its ability to utilize sucrose and lactose confirmed the similarity of BTAi 1 to other fast growers. However, its inability to utilize rhamnose, dulcitol, raffinose, trehalose, citrate, malate and fumarate linked it to the slow-growing rhizobia. The absence of the pentose phosphate pathway also placed BTAi 1 with the slow-growers as did the presence of 2-keto-3-deoxy-L-arabonate aldolase, its small colony morphology and the production of alkali with most carbon sources. Strain BTAi 1 is thus an intermediate type of *Rhizobium*, sharing characteristics with both fast and slow growers.

**INTRODUCTION**

There is much information regarding the biology of economically important *Rhizobium*-legume associations, but little is available concerning the more obscure interactions, such as the stem nodule symbiosis of *Aeschynomene* species (Yatazawa & Yoshida, 1979).

Any future study of the *Rhizobium*-*Aeschynomene* symbiosis must be complemented by basic information regarding the physiology of the microsymbiont. Little is known of the physiology of *Aeschynomene* root- or stem-nodule isolates (Allen & Allen, 1981; Subba Rao et al., 1980; Yatazawa & Yoshida, 1979), but they appear to belong to the slow-growing group of rhizobia probably in the cowpea miscellany (Allen & Allen, 1981; Date & Halliday, 1980). Stem nodules also occur on *Sesbania rostrata* (Dreyfus & Dommergues, 1981a, b) and the infecting *Rhizobium* is reported to be fast-growing (Y. R. Dommergues, personal communication).

Rhizobia are classified primarily as fast or slow growers in yeast extract/mannitol broth (Allen & Allen, 1950; Jordan & Allen, 1974) and on their enzymes of carbon metabolism (Martinez-De Drets & Arias, 1972). In order to establish the fundamental characteristics of these stem-nodulating rhizobia for comparison with other types, this communication describes nutritional and enzymic studies.

**METHODS**

*Rhizobia.* *Rhizobium* strain BTAi 1, was isolated from a submerged stem nodule on greenhouse-grown *Aeschynomene indica* (Eaglesham & Szalay, 1983). These nodules were discovered on *A. indica* plants grown in non-sterilized sand from surface-sterilized seeds, but did not occur on plants grown in sterilized sand. We concluded that the rooting medium (quartz sand from the Pennsylvania Glass Sand Corporation, Pittsburgh, U.S.A.) was the source of the rhizobia. The sand had been mined as quartzite from an open pit mine in West Virginia with contamination from surface soil (J. McDonough, personal communication). It may be significant that *A. virginica*

† Present address: Native Plants, Salt Lake City, Utah 84108, U.S.A.

**Abbreviations:** KDA aldolase, 2-keto-3-deoxy-L-arabonate aldolase; PFK, phosphofructokinase; 6PG dehydrogenase/dehydratase, 6-phosphogluconate dehydrogenase/dehydratase.
is indigenous from New Jersey to S. E. Virginia (Gleason, 1952). Strain BTAi 1 nodulated the roots as well as the stems of several **Aeschynomene** species (Eaglesham & Szalay, 1983).

The isolate was maintained on agar slants and transferred every three months. Infectivity was checked on the stems of **A. scabra** on which nodules appeared 4–6 d after inoculation (Eaglesham & Szalay, 1983).

**Rhizobium** sp. strain IRc 256 was obtained from the IJTA Collection of Cultures of **Rhizobium**, Ibadan, Nigeria, and **Rhizobium** sp. strain 32H1 from the Nitragin Co., Milwaukee, Wis., U.S.A. These are slow-growing strains of the cowpea miscellany; IRc 256 was isolated from **Vigna unguiculata** and 32H1 from **Crotolaria paulina**. **Rhizobium leguminosarum** strain ATCC 10004 was obtained from the American Type Culture Collection, Rockville, Md., U.S.A.

**Media.** The basal growth medium consisted of the following (g l−1): K2HPO4, 0.5; MgSO4.7H2O, 0.8; NaCl, 0.2; FeCl3.6H2O, 0.01; mannitol, 10; yeast extract, 1.0; and, for solidified medium, agar was added to a final concentration of 2 % (w/v) (Norris & Date, 1976). When other carbon sources replaced mannitol, they were either autoclaved separately (galactose, gluconate, glycerol, mannose, rhamnose and xylose) or filter sterilized (arabinose, citrate, fructose, fumarate, glucose, malate, pyruvate, raffinose, succinate and trehalose) and then added to the medium to a final concentration of 1 % (w/v).

**Nutritional characteristics.** Carbon nutrition was determined using an agar-plate method with the basal growth medium and yeast extract and the appropriate carbon source. Growth on control plates was attributed to the utilization of yeast extract as the sole carbon source. Growth with a particular carbon source was determined after 5 d by comparison with control agar plates where the major carbon source was omitted. The analysis of growth by this method was required since strain BTAi 1 did not grow well on inorganic nitrogen. Acid or alkali production was determined by colour change of bromthymol blue, which was incorporated into the agar medium at a final concentration of 0.00125 % (w/v).

**Preparation of cell-free extracts.** Cells were harvested by centrifugation, washed twice in cold 50 mm-sodium phosphate buffer pH 7.0 and then added to a final concentration of 2 % (w/v). Generation times were determined from exponential phase cells by viable counts.

**Enzyme assays.** Published procedures were used to assay glucose-6-phosphate (G6P), 6-phosphogluconate (6PG) dehydrogenases (EC 1.1.1.49 and 1.1.1.44, respectively) and phosphofructokinase (PFK) (EC 2.7.1.11) (Stowers & Elkan, 1983), isocitrate dehydrogenase and malate dehydrogenase (EC 1.1.1.42 and EC 1.1.1.37, respectively) (Rokosh et al., 1973) and 2-keto-3-deoxy-l-arabonate (KDA) aldolase (EC 4.1.2.18) (Pedrosa & Zancan, 1974). The Entner–Doudoroff enzymes were determined as the coupled activity of 6PG dehydrolase (EC 4.2.1.12) and 2-keto-3-deoxy-6-phosphogluconate aldolase (EC 4.1.2.14) as described by Lessie & Vander Wyk (1972).

**RESULTS**

**Growth and nutritional characteristics**

After 7 d growth on yeast mannitol agar, colonies of BTAi 1 were less than 1 mm in diameter, circular with an entire margin and white with a slightly convex elevation. This type of colony morphology is typical of the slow-growing rhizobia (Graham & Parker, 1964).

Strain BTAi 1 grew best on hexoses, but also used pentoses, glycerol and the disaccharides, sucrose and lactose (Table 1). It was unable to use the TCA cycle intermediates malate and fumarate and grew poorly on succinate. Acid production occurred only with arabinose and xylose, whereas the other carbon sources caused increases in pH. For comparison, the nutritional characteristics of the fast-grower **R. leguminosarum** strain ATCC 10004 and the slow-grower **Rhizobium** sp. IRc 256 are included in Table 1 to show patterns typical of fast and slow growers (Vincent, 1977). Marked similarities were found between BTAi 1 and IRc 256. Both strains failed to use rhamnose, dulcitol, raffinose, trehalose, citrate, malate and fumarate. In contrast, ATCC 10004 used all these compounds. The final culture pH reactions were almost identical with BTAi 1 and IRc 256, but with strain ATCC 10004 only acid reactions were obtained.
Table 1. *Carbohydrate nutritional characteristics of Rhizobium strain BTAi 1 in comparison to Rhizobium sp. strain IRc 256 and R. leguminosarum strain ATCC 10004*

+ , Better growth than in the control without carbon; – , growth equal to the control without carbon; alkaline, pH >6·8, or blue reaction with bromthymol blue; acid, pH <6·8, or yellow reaction with bromthymol blue.

Strain BTAi 1 had the fastest growth rate with glucose, with a generation time of 3·2 h (Table 2). When growing with mannitol, its generation time was 4·0 h (Table 2), comparable to the 2·8 h obtained with strain ATCC 10004. The growth rates of BTAi 1 were faster than expected based on its carbon nutrition patterns and final culture alkaline pH reactions, which were
characteristic of slow-growing rhizobia, i.e. those with generation times exceeding 6 h (Jordan & Allen, 1974; Vincent, 1977). Strain IRC 256 had a generation time of 9.3 h with mannitol. Strain BTAi 1 had its slowest growth rate when cultured with succinate (Table 2) and it is interesting to note that the highest growth rates previously reported for fast-growing rhizobia have been with succinate (Ucker & Signer, 1978).

**Enzymes of carbon metabolism**

There was no evidence for the presence of the pentose phosphate pathway, since cell-free extracts lacked the NADP-linked 6PG dehydrogenase (Table 2). Likewise, no activity was detected for PFK indicating the lack of the Embden–Meyerhof–Parnas pathway. Therefore, the sole routes of metabolism of mannitol, glucose and sucrose were by the Entner–Doudoroff pathway and the TCA cycle, the former revealed by the G6P dehydrogenase and Entner–Doudoroff enzyme activities and the latter by the isocitrate and malate dehydrogenase activities. Extracts from *Rhizobium* sp. 32H1 were run simultaneously as controls, and enzyme activities were identical to those previously reported (Stowers & Elkan, 1983). The pathway for arabinose catabolism was the same as that described for slow-growing *Rhizobium japonicum* as shown by the presence of KDA aldolase (Pedrosa & Zancan, 1974).

**DISCUSSION**

A stem-nodule *Rhizobium* previously isolated from *Aeschynomene indica* strain BTAi 1 (Eaglesham & Szalay, 1983), was the subject of this study. It was chosen for its ability to nodulate only *Aeschynomene* species (Legocki et al., 1983) hence exemplifying the characteristics of rhizobia which form the unusual stem nodule symbiosis.

Strain BTAi 1 showed metabolic characteristics which are common to both fast- and slow-growing rhizobia, such as the absence of the Embden–Meyerhof–Parnas pathway and the presence of the Entner–Doudoroff pathway and TCA cycle for carbon catabolism (Martinez-De Drets & Arias, 1972; Elkan & Kuykendall, 1982). Past attempts to delineate rhizobia have resulted in two main groupings based primarily on growth rate and final culture pH of cells grown in yeast extract/mannitol broth (reviewed by Vincent, 1977). Acid production has been linked to fast-growing rhizobia and alkali production to slow-growing rhizobia (Norris, 1965). The alkaline reactions observed with BTAi 1 (Table 1) were characteristic of slow-growing rhizobia (Jordan & Allen, 1974). Enzymic differences have also contributed to the distinction of fast and slow growers (Martinez-De Drets & Arias, 1972).

The growth rate of BTAi 1 and its ability to utilize disaccharides for growth placed it with the fast-growing rhizobia (Jordan & Allen, 1974; Vincent, 1977). On the other hand, the colony morphology, the alkaline final culture pH, inability to use TCA cycle intermediates as sole carbon source, the absence of an NADP-linked 6PG dehydrogenase, and the presence of an arabinose catabolic pathway possessing KDA aldolase and an acid end product, grouped this isolate with slow-growing rhizobia (Jordan & Allen, 1974). In contrast, the *Sesbania* stem nodule bacterium, ORS 571, did not grow with mannitol as the sole carbon source and preferred TCA cycle intermediates for growth (Y. R. Dommergues, personal communication).

This *Rhizobium* strain which nodulates the stems of *Aeschynomene* species is an example of an intermediate type sharing physiological properties of both fast and slow growers. Another intermediate-type *Rhizobium* isolated from *Leucaena leucocephala*, has recently been reported (Tan & Broughton, 1981). With regard to growth rate, acid production and carbohydrate utilization patterns it was characterized as a fast grower, while it had a metabolic preference for glutamate as nitrogen source, a characteristic usually found in slow growers (Tan & Broughton, 1981, 1982). In addition, this isolate possessed a single sub-polar flagellum, as did strain BTAi 1, (M. D. Stowers & A. R. J. Eaglesham, unpublished) linking it to the slow-growing group of rhizobia. It is clear that the separation between fast- and slow-growing rhizobia is not as distinct as once thought.

We thank Suzette Payne for typing the manuscript.
Physiologically intermediate Rhizobium
