(Received 16 June 1987; revised 3 November 1987)

We report the nucleotide sequence of a 1.45 kb segment containing the \emph{eta} gene, coding for staphylococcal exfoliative toxin A (ETA), isolated from the recombinant plasmid pETA-J3. The coding region of 840 bp specified a polypeptide of 280 amino acid residues which included a putative 38 residue signal sequence. The amino acid composition deduced from the structural gene was in agreement with the results of peptide analysis of the ETA molecule reported by others. The sequence of the 35 N-terminal amino acid residues of ETA derived from \emph{Staphylococcus aureus} strain ZM was also consistent with that deduced from the DNA sequencing.

\section*{INTRODUCTION}

Infection of human neonates with certain \emph{Staphylococcus aureus} strains can cause Ritter's disease, also known as the staphylococcal scalded skin syndrome (SSSS). Since Melish \& Glasgow (1970) established a mouse model for bioassay of SSSS, rapid progress has been made in molecular studies of the disease, and it is now well established that the exfoliative toxin (ET) is the causative agent of SSSS (Melish \& Glasgow, 1970; Kapral \& Miller, 1971; Arbuthnott \textit{et al}. 1971; Kondo \textit{et al}., 1973, 1974, 1975). The most conclusive evidence for this is that administration of highly purified ET to mice reproduces the typical Nikolsky sign (NK), exfoliation of the epidermis seen in patients with Ritter's disease. Some inbred mice are able to produce antibodies to ET while others are non-producers. However, all mouse strains so far tested are susceptible to this toxin (Kondo \& Sakurai, 1980). Therefore, the mechanism of ET pathogenesis is independent of the immune response of the hosts. When rabbits were immunized with ET, a new toxin serotype (ETB), non-crossreactive to the existing ET (ETA), was discovered (Kondo \textit{et al}., 1973). Structural differences between serotypes ETA and ETB are further suggested by differences in heat stability (Kondo \textit{et al}., 1973, 1974). Also ETA is a metallo-toxin, containing one copper ion per molecule, whereas no metal is detectable in the ETB molecule (Kondo \& Sakurai, 1980). ETA is heterogeneous in isoelectric point while ETB is homogeneous (Kondo \textit{et al}., 1974). In addition, ETA is coded by a chromosomal gene while ETB is plasmid-specified (Rogolsky \textit{et al}., 1974, 1976; Wiley \& Rogolsky, 1977; Jackson \& Iandolo, 1986; O'Toole \& Foster, 1986a, b).

Although ETA and ETB are antigenically distinct, they presumably share some structures important for toxinogenesis. Therefore, we cloned the gene coding for ETA, \emph{eta}, into pUC9 and transformed \emph{Escherichia coli} C600 with the recombinant plasmid pETA, in order to analyse the properties of ETA. ETA produced by the \emph{E. coli} transformant, cETA, was indistinguishable from the ETA produced by \emph{Staphylococcus aureus}, sETA, in its physicochemical and serological properties and its ability to cause exfoliation. cETA did not remain in the periplasmic space of the \emph{E. coli} transformants, and more than 97\% of the toxin became extracellular (Sakurai \textit{et al}., 1987).

\textit{Abbreviations}: ETA, ETB, exfoliative toxin A, B; ORF, open reading frame.
Fig. 1. Restriction map and sequencing strategy of the AluI–TaqI fragment of pETA-J3. Abbreviations of restriction endonucleases are as follows: A, AluI; B, BamHI; E, EcoRI; Q, TaqI; S, Sau3AI; R, RsaI; D, DraI. The arrows indicate the DNA segments inserted into the replicative-form DNA of M13mp18 for sequencing.

In this communication, we report the sequence of the entire coding region as well as the putative promoter of \( \text{eta} \). We have also determined the N-terminal amino acid sequence of sETA protein.

**METHODS**

**Bacterial strains and media.** \( S. \text{aureus} \) strain ZM, an ETA-producing strain, and \( E. \text{coli} \) transformant strain Ceta, carrying the cloned \( \text{eta} \) gene, were as described previously (Kondo et al., 1973; Sakurai et al., 1987). Phage M13mp18 and \( E. \text{coli} \) JM109 were included in a sequencing kit obtained from Takara Shuzo (Tokyo).

ET-broth (Sakurai et al., 1987) and L-broth (Miller, 1972) were used for growth of \( S. \text{aureus} \) and \( E. \text{coli} \) respectively. ET-agar and L-agar were also prepared by adding 15 g or, for soft agar, 5 g purified agar to 1 litre of ET-broth and L-broth, respectively.

**DNA sequencing.** The recombinant plasmid, pETA-J3, was described previously (Sakurai et al., 1987). A 1.45 kb DNA fragment containing the \( \text{eta} \) gene was isolated from pETA-J3 by AluI and TaqI digestion. This segment was cleaved with restriction endonucleases AluI, TaqI, Sau3AI, RsaI and DraI to give fragments of suitable size for sequencing. These were ligated to the replicative-form DNA of M13mp18 and used to transfect \( E. \text{coli} \) JM109. The phages isolated from colourless plaques were used to infect JM109. Single-stranded DNA was purified and sequenced by the dideoxy chain termination method (Sanger et al., 1977, 1980; Sanger, 1981; Messing & Vieira, 1982) using \( [\sigma^{32}\text{P}] \text{dCTP} \) (ICN Radiochemicals). The DNA sequence was analysed using the DNASIS computer program (Hitachi Software Engineering Co.).

**Determination of N-terminal amino acid sequence of ETA.** The ETA produced by \( S. \text{aureus} \) strain ZM was purified by HPLC on a Hitachi 3013-0 column, and subjected to N-terminal sequence determination by the method of Tarr (1986) with a gas-phase protein sequencer (model 470A, ABI Co.) and on-line PTH amino acid analyser (model 120A PTH Analyzer, ABI Co.).

**RESULTS AND DISCUSSION**

**Nucleotide sequence of the \( \text{eta} \) gene.** The restriction map of the \( \text{eta} \) fragment and the sequencing strategy are shown in Fig. 1. The nucleotide sequence of the 1454 bp fragment containing the \( \text{eta} \) gene was obtained in both strands (Fig. 2). One open reading frame (ORF), extending from residue 374 to residue 1213, was identified by computer analysis. The TAA codon at position...

Table 1. *N*-terminal amino acid sequence of ETA from *S. aureus* strain ZM

The sequence shown was determined chemically. It is identical to that deduced from the *eta* nucleotide sequence, the N-terminal Glu residue corresponding to the 39th amino acid in the sequence shown in Fig. 2.

* Johnson *et al.* (1979) sequenced the N-terminus of ETA from *S. aureus* strain TA, as far as residue 23. That sequence was identical to the one shown except for the amino acids in parentheses.

*N*-terminal amino acid sequence and putative signal peptide. The 35 amino acid residues constituting the N-terminal sequence of mature ETA purified from *S. aureus* ZM culture supernate were determined (Table 1). The first amino acid, glutamic acid (E), corresponds to the 39th residue in the amino acid sequence deduced from the nucleotide sequence of the cloned *eta* gene; the following 34 residues were identical to those deduced from the DNA sequence. Since the 39th amino acid was identified as the N-terminal residue of the mature toxin, the signal sequence is presumed to consist of the preceding 38 amino acid residues (Fig. 2).

The hydropathy profile of the *eta* gene product (Fig. 3) shows that the N-terminal sequence contains a markedly hydrophobic stretch in the middle. Although this putative signal peptide is long, it is still within the range for a signal peptide of a protein excreted from Gram-positive bacteria. For example, protein A contains a signal sequence of 36 amino acid residues (Uhlen *et al*., 1983) whereas ETB has 31 (Jackson & Iandolo, 1986).

Molecular mass and amino acid composition of ETA predicted from the DNA sequence. The amino acid composition of ETA predicted from the *eta* gene structure is in close agreement with that of ETA derived from *S. aureus* strain TA reported by Johnson *et al.* (1979), with only minor differences: the predicted *eta* gene product contains four more Val residues, two more Leu residues and one more Gly residue, but two fewer Glu + Gln residues. The total number of amino acid residues of the predicted *eta* gene product is 242, five more than reported by Johnson *et al.* (1979). The molecular mass of ETA calculated from these 242 amino acids (26.9 kDa) is somewhat larger than that (24 kDa) estimated by gel filtration in our previous experiments (Kondo *et al*., 1973).

Potential secondary structure in the 5' and 3' flanking regions of the *eta* gene. The 5' flanking regions contain two inverted repeats (Figs 2 and 4). Both partially overlap the -10 region of the putative promoters and thus may play regulatory roles. Inverted repeats were also identified at two positions in the 3' flanking region: the one farthest from the ORF was GC rich and was followed by seven T residues; it may correspond to a p-dependent transcription terminator (Rosenberg & Court, 1979).

In conclusion, several characteristic structures of the *eta* gene and its product were identified: double promotor regions, two inverted sequences in both the 5' and the 3' flanking regions, a long signal sequence consisting of 38 amino acid residues, and an N-terminal segment...
DNA sequence of S. aureus toxin gene

Fig. 3. Hydropathy profile of the eta gene product. The vertical axis indicates the relative hydrophobicity (negative values) or relative hydrophilicity (positive values). The horizontal axis denotes the amino acid residues, numbered from the first amino acid of the primary eta gene product. Each interval between two dots in the dotted horizontal lines corresponds to four amino acid residues. Hydrophobicity of the derived cETA protein was determined according to Kyte & Doolittle (1982) using a window of four amino acid residues.

Fig. 4. Inverted sequences in the 5' and 3' flanking regions of the ETA coding sequence. (a, b) Inverted sequences upstream of the presumed SD sequence. Promoter-like sequences (-35 and -10 regions) are indicated by lines above the respective hexanucleotides. Note that both -10 regions overlap the inverted sequences. (c, d) Inverted sequences in the 3' flanking region of the eta gene. The numbers in parentheses are amino acid sequence numbers. The stop codon is marked with asterisks. Nucleotide sequence numbers (see Fig. 2) are also shown.
containing a markedly hydrophobic region in the middle. However, it is not yet known what domains in the nucleotide sequence of this gene play essential roles in coding for the biological properties of ETA.

We have recently cloned the gene coding for ETB (etb) and determined the DNA sequence (unpublished results). It was different from the etb sequence reported by Jackson & Iandolo (1986), but Lee et al. (1987) have presented a revised DNA sequence of etb in addition to the sequence of the eta gene, and our data on eta are in agreement with their eta sequence except for minor differences in 5' and 3' flanking regions. The DNA sequence of etb which we recently obtained is also in agreement with their revised etb sequence. The comparative analyses between the eta and etb genes cloned in our department are now being carried out.

This work was partially supported by a grant-in-aid for special project no. 60108603 from the Ministry of Education, Science and Culture, Japan. We thank Professor N. Yamamoto, Department of Microbiology and Immunology, Hahneman University School of Medicine, for his kind discussion of this work and also thank Miss R. Nakayama for technical assistance.
