The genes *glpK* and *glpF*, encoding glycerol kinase and the glycerol facilitator of *Thermus flavus*, a member of the Thermus/Deinococcus group, have recently been identified. The protein encoded by *glpK* exhibited an unusually high degree of sequence identity (80%) when compared to the sequence of glycerol kinase from *Bacillus subtilis* and a similar high degree of sequence identity (64%) was observed when the sequences of the glycerol facilitators of the two organisms were compared. The work presented in this paper demonstrates that *T. flavus* is capable of taking up glycerol, that *glpF* and *glpK* are expressed constitutively and that glucose exerts a repressive effect on the expression of these genes. *T. flavus* was found to possess the general components of the phosphoenolpyruvate (PEP):sugar phosphotransferase system (PTS) enzyme I and histidine-containing protein (HPr). These proteins catalyse the phosphorylation of *T. flavus* glycerol kinase, which contains a histidyl residue equivalent to His-232, the site of PEP-dependent, PTS-catalysed phosphorylation in glycerol kinase of *Enterococcus casseliflavus*. Purified glycerol kinase from *T. flavus* could also be phosphorylated with enzyme I and HPr from *B. subtilis*. Similar to enterococcal glycerol kinases, phosphorylated *T. flavus* glycerol kinase exhibited an electrophoretic mobility on denaturing and non-denaturing polyacrylamide gels that is different from the electrophoretic mobility of non-phosphorylated glycerol kinase. However, in contrast to PEP-dependent phosphorylation of enterococcal glycerol kinases, which stimulated glycerol kinase activity about 10-fold, phosphorylation of *T. flavus* glycerol kinase caused only a slight increase in enzyme activity.

**Keywords:** *Thermus flavus*, glycerol metabolism, glycerol kinase, PEP:sugar phosphotransferase system
play an important role in the regulation of glycerol metabolism in numerous bacteria. The mechanisms involved in this regulation are different in Gram-positive and Gram-negative bacteria, but they are both mediated via glycerol kinase. In Gram-negative bacteria such as *Escherichia coli* or *Salmonella typhimurium*, EIAlia was found to interact with glycerol kinase (Hurley et al., 1993) and to inhibit its activity (De Boer et al., 1986; van der Vlag et al., 1994) leading to reduced uptake of glycerol. In contrast, phosphorylated EIAlia had no inhibitory effect on glycerol kinase activity. In Gram-positive bacteria such as *Enterococcus faecalis* and *Enterococcus casseliflavus*, glycerol kinase was found to be phosphorylated by PEP, enzyme I and HPr, and phosphorylation caused an ~10-fold increase of glycerol kinase activity (Deutscher, 1985; Deutscher & Sauerwald, 1986; Charrier et al., 1997). This phosphorylation is reversible, and phosphorylated glycerol kinase is dephosphorylated probably by transferring its phosphoryl group to HPr when a rapidly metabolizable PTS substrate is present in the growth medium leading to dephosphorylation of the PTS proteins (Deutscher et al., 1993). Recently, His-232 of glycerol kinase from *Ent. casseliflavus* has been identified as the site of PEP-dependent phosphorylation (Charrier et al., 1997). In glycerol kinase of *Bacillus subtilis*, the equivalent His-230 is probably also phosphorylated. Mutants in which His-230 had been replaced with an arginine or in which the neighbouring Phe-232 had been replaced with a serine were able to grow on glycerol as the sole carbon source, even when the general PTS proteins enzyme I and HPr were not functional (Wehtje et al., 1995). Glycerol kinase in these mutants was therefore assumed to possess elevated activity, rendering glycerol uptake and metabolism independent of PTS-mediated activation by phosphorylation. This could indeed be confirmed for the His-232-Arg mutant glycerol kinase of *Ent. casseliflavus*, which exhibited much higher activity than the wild-type enzyme (Charrier et al., 1997). An amino acid sequence comparison with known glycerol kinase sequences derived from Gram-positive and Gram-negative bacteria revealed that these enzymes exhibit sequence identities ranging from about 40 to 60% when compared to each other, but that the phosphorylatable histidyl residue and the flanking sequences are well-conserved only in glycerol kinases of Gram-positive bacteria, whereas an equivalent of the phosphorylatable histidyl residue is absent from glycerol kinases of Gram-negative bacteria such as *Es. coli* and *Haemophilus influenzae* (Charrier et al., 1997).

Recently, *glpK*, the gene encoding glycerol kinase, and a fragment of *glpF*, which encodes the first 156 amino acids of the glycerol facilitator of *Thermus flavus*, have been cloned and sequenced (Huang et al., 1998a). Surprisingly, the thermostable glycerol kinase from *T. flavus*, which belongs to the Thermus/Deinococcus group, showed an unusually high degree of sequence identity (80-6%) when compared to glycerol kinase of *B. subtilis* and 64-0% when compared to glycerol kinase of *Ent. casseliflavus*. An equivalent of His-232, the site of PEP-dependent phosphorylation in glycerol kinase from *Ent. casseliflavus*, is present in glycerol kinase of *T. flavus* and the surrounding sequence is well-conserved. We therefore wanted to study whether *T. flavus* is capable of transporting glycerol and whether glucose exerts a repressive effect on glycerol transport and metabolism. We also wanted to test whether *T. flavus* possesses the general PTS components enzyme I and HPr allowing PEP-dependent phosphorylation of purified *T. flavus* glycerol kinase, whether purified enzyme I and HPr from *B. subtilis* can phosphorylate *T. flavus* glycerol kinase and whether this PEP-dependent phosphorylation would have an influence on *T. flavus* glycerol kinase activity.

**METHODS**

**Strains and growth conditions.** *T. flavus* strain TE3420 (DSM 674) (Huang et al., 1998a) was obtained from the Deutsche Sammlung von Mikroorganismen und Zellkulturen GmbH, Braunschweig, Germany. It was grown with shaking at 50 °C in 2 × YT medium (Sambrook et al., 1989) in the absence of carbohydrates or in the presence of either 1% glycerol, 1% glucose, or 1% glycerol plus 1% glucose. *E. coli* strains M15 (containing the plasmid pREP4; Qiagen) and DH5α (containing plasmid pGKY12) (Huang et al., 1997, 1998a) were grown at 37 °C in Luria–Bertani (LB) medium (Sambrook et al., 1989). For the growth of cells transformed with the plasmids pREP4 and either pAG2 or pAG3 (Galiner et al., 1997), the LB medium also contained 25 µg kanamycin ml⁻¹ and 100 µg ampicillin ml⁻¹.

**Protein purification.** Recombinant *T. flavus* glycerol kinase was produced in the *Esc. coli* strain DH5α transformed with plasmid pGKY12 and purified by sequential chromatography on DEAE-Toyopearl and Toyopearl HW650 columns as previously described (Huang et al., 1997, 1998a). The *Esc. coli* strain M15 carrying the plasmid pREP4 (Qiagen) and transformed with plasmids pAG2 or pAG3 was used for the overproduction of *B. subtilis* His-tagged HPr and His-tagged enzyme I, respectively (Galiner et al., 1997).

**Glycerol-transport assay.** A 150 ml culture of *T. flavus* TE3420 cells was grown to mid-exponential phase and cells were harvested by centrifugation at 4 °C, washed twice with MM medium (Anagnostopoulos & Spizizen, 1961) and resuspended in the same medium at a concentration corresponding to an OD₆₅₀ of 2. A peptone solution was added (1% final concentration) and the mixture was warmed at 50 °C for 10 min before (1,3,13-C)glycerol ([CN]; 0.5 mM final concentration, specific activity, 0.5 mCi (18.5 MBq) mmol⁻¹) was added. Aliquots (120 µl) were withdrawn at different time intervals (0.5, 1.5, 3, 5, 10, 15 and 20 min), filtered through a 0.45 µm pore-size filter and washed twice with 5 ml cold Tris/maleate buffer, pH 7.4. The filters were dried and the radioactivity retrieved was determined by liquid scintillation counting.

**Protein-phosphorylation assays.** Phosphorylation of purified *T. flavus* glycerol kinase with crude extracts prepared from *T. flavus* cells was carried out with [³²P]PEP, which was prepared from [γ⁻³²P]ATP via the pyruvate kinase exchange reaction at equilibrium (Roosien et al., 1983). *T. flavus* cells were grown in 150 ml 2 × YT medium in the absence of a carbohydrate or in the presence of 1% glycerol, 1% glucose or 1% fructose to OD₆₅₀ between 0.65 and 0.70. Cells were centrifuged, washed

three times with 50 mM Tris/HCl buffer, pH 7.4, resuspended in 2 ml of the same buffer and broken by sonication. Cell debris was removed by centrifugation and the supernatant was dialysed overnight against 50 mM Tris/HCl, pH 7.4, containing 0.1 mM PMSF and 0.1 mM DTT. Phosphorylation of glycerol kinase was carried out in a reaction mixture of 30 µl containing 4 µg T. flavus glycerol kinase, 10 mM MgCl₂, 10 µM [32P]PEP (0.1 µCi; 3.7 kBq), 50 mM Tris/HCl buffer, pH 7.4, and 6 µl T. flavus crude extracts. The assay mixture was incubated for 20 min at 37 °C. The phosphorylation reaction was stopped by adding an equal volume of sample buffer (Laemmli, 1970) to the assay mixtures. Phosphorylation reaction was stopped by adding an equal volume of sample buffer (Laemmli, 1970) to the assay mixtures. Enzyme activities are expressed as nmol product formed min⁻¹.

Enzyme-activity assays. Glycerol kinase activity was determined by using a coupled spectrophotometric assay carried out in 100 mM glycine/hydrazine buffer, pH 8.8 (Deutscher & Sauerwald, 1986). Enzyme activities are expressed as mmol product formed min⁻¹ and (µg protein)⁻¹. To measure the effect of phosphorylation on the enzyme activity, glycerol kinase (64 µg) was first incubated for 20 min at 37 °C together with 10 mM PEP, 10 mM MgCl₂, 1 µg enzyme I(His)₄, and 1 µg HPr(His)₃ in a total volume of 60 µl. An aliquot of 7.5 µl of the reaction mixture (corresponding to 0.5 µg enzymic glycerol kinase) was used for the glycerol kinase assay. To determine to what extent glycerol kinase used in these enzymic tests was phosphorylated, the proteins present in a 30 µl aliquot of the glycerol kinase phosphorylation mixture were separated on a denaturing 10% polyacrylamide gel.

The presence of enzyme I and HPr in crude extracts of T. flavus has been demonstrated with the Staphylococcus aureus mutant complementation assay by using crude extracts prepared from the mutants S710A (ptoI lacR) and S797A (ptoH lacR) (Hengstenberg et al., 1969).

RESULTS

T. flavus is capable of taking up glycerol

We first wanted to test whether T. flavus is able to transport glycerol. For this purpose, T. flavus cells were grown in 2× YT medium or 2× YT medium containing glycerol, glucose or glycerol plus glucose. Cells grown in 2× YT or 2× YT containing glycerol were found to transport glycerol effectively (Fig. 1), suggesting that the T. flavus glpF gene and the adjacent glpK gene, which encode the glycerol facilitator and glycerol kinase, respectively, and which were found to be organized in an operon (Huang et al., 1998a), are expressed constitutively. In contrast, cells grown in 2× YT medium containing either glucose or glucose plus glycerol exhibited strongly reduced glycerol uptake, indicating that a carbon-catabolite repression mechanism is operative in T. flavus.

Phosphorylation of T. flavus glycerol kinase

Since the glycerol kinases from T. flavus (Huang et al., 1998a) and Thermus aquaticus (Huang et al., 1998b) exhibit an unusually high degree of sequence identity when compared to glycerol kinase from Ent. casseli-flavus (about 65%) or B. subtilis (more than 80%), and since the sequence around the histidyl residue representing the site of PEP-dependent phosphorylation in glycerol kinases of Gram-positive bacteria is well-conserved in glycerol kinase from T. flavus (Fig. 2), we wanted to test whether T. flavus possesses enzyme I and HPr capable of catalysing the PEP-dependent phosphorylation of purified T. flavus glycerol kinase. To determine whether enzyme I and HPr are present in T. flavus, we carried out a mutant-complementation assay with crude extracts from the S. aureus ptoI lacR mutant S710A or the ptoH lacR mutant S797A, respectively. Crude extracts from T. flavus cells grown on 2× YT were capable of restoring PTS-catalysed ONPG phosphorylation in both S. aureus mutants (data not shown), confirming that T. flavus must possess enzyme I and HPr. The positive results suggested also that enzyme I and HPr from T. flavus resemble their Gram-positive homologues since the corresponding proteins of Gram-negative bacteria are not functional in the S. aureus mutant-complementation assay (Kalbitzer et al., 1982).

**Fig. 1.** Uptake of [14C]glycerol by T. flavus cells. Cells were grown in 2× YT medium without an additional carbon source (■) or with 1% glycerol (■), 1% glucose (●) or 1% glycerol plus 1% glucose (▲). Glycerol-transport studies were carried out in MM medium containing 1% peptone and 0.5 mM [32P]PEP or stained with Coomassie brilliant blue R for experiments with non-radioactive PEP.
To test whether *T. flavus* enzyme I and HPr would be capable of phosphorylating the glycerol kinase of this organism, *T. flavus* cells were grown in 2 × YT medium in the absence of a carbohydrate or in the presence of 1% glycerol, 1% glucose or 1% fructose and crude extracts were prepared from these cells as described in Methods. These crude extracts were used for PEP-dependent phosphorylation assays. After incubation with [32P]PEP in the absence of purified glycerol kinase, four major phosphorylated proteins were found to be present in crude extracts of *T. flavus* cells grown in 2 × YT medium or 2 × YT medium containing either glycerol or fructose (Fig. 3a, lanes 3, 5 and 9). Two of these labelled bands migrated similarly to the *B. subtilis* enzyme I and HPr standards (Fig. 3a, lane 1) and probably represent the corresponding *T. flavus* proteins. The third labelled band migrated just below the presumed enzyme I band, while the fourth band migrated according to a molecular mass of 55 kDa, which is in good agreement with the molecular mass calculated for glycerol kinase monomers from *T. flavus*. While the first three labelled bands exhibited similar intensities in glucose-grown cells, the intensity of the fourth band was clearly reduced in glucose-grown cells (Fig. 3a, lane 7). However, the intensity of the radioactive band migrating according to a molecular mass of 55 kDa was greatly increased when purified *T. flavus* glycerol kinase was added to the phosphorylation assays with the various crude extracts (Fig. 3a, lanes 2, 4, 6 and 8). These results establish that *T. flavus* possesses the general PTS components enzyme I and HPr and that these two proteins are capable of phosphorylating *T. flavus* glycerol kinase.

**Purified *T. flavus* glycerol kinase can be phosphorylated by enzyme I and HPr from *B. subtilis***

As the general PTS components of *T. flavus* are not available in purified form and as *T. flavus* glycerol kinase exhibits the general homology to glycerol kinase from *B. subtilis* (more than 80% sequence identity), we wanted to test whether *T. flavus* glycerol kinase could be phosphorylated with PEP in the presence of enzyme I(His) and HPr(His) from *B. subtilis*. PEP-dependent phosphorylation of *T. flavus* glycerol kinase catalysed by enzyme I and HPr of *B. subtilis* was demonstrated either by phosphorylation with [32P]PEP followed by separation on an SDS-polyacrylamide gel and autoradiography or by phosphorylation in the presence of 10 mM PEP followed by separation on either denaturing or nondenaturing polyacrylamide gels. Using [32P]PEP, we could demonstrate that purified *T. flavus* glycerol kinase was phosphorylated in the presence of PEP, enzyme I(His) and HPr(His) (Fig. 3b, lane 4). No radioactive band corresponding to phosphorylated glycerol kinase appeared when either enzyme I(His) or HPr(His) were absent (Fig. 3b, lanes 5 and 7), confirming that phosphorylation of *T. flavus* glycerol kinase requires both general PTS proteins. Similar to enterococcal glycerol kinases (Deutscher, 1985; Charrier et al., 1997), the phosphorylated and unphosphorylated forms of *T. flavus* glycerol kinase were found to migrate to different positions during SDS-PAGE (Fig. 3c, lanes 1 and 4). The more slowly migrating band corresponding to phosphorylated glycerol kinase was absent when either HPr, enzyme I or PEP were missing in the reaction mixture (Fig. 3c, lanes 2, 3 and 5). Phosphorylated and unphosphorylated *T. flavus* glycerol kinase also exhibited a different electrophoretic mobility when they were separated on non-denaturing polyacrylamide gels, where phosphorylated glycerol kinase was found to migrate faster than unphosphorylated glycerol kinase (Fig. 3d, lanes 1 and 4). Again, the band corresponding to phosphorylated glycerol kinase was absent when either HPr, enzyme I or PEP were missing in the reaction mixture (Fig. 3d, lanes 2, 3 and 5). In phosphorylation assays containing PEP at concentrations higher than 10 µM, only the faster-migrating band corresponding to phosphorylated glycerol kinase could be observed. With PEP at concentrations lower than 1 µM, only the band corresponding to unphosphorylated glycerol kinase was visible (data not shown). Interestingly, three bands corresponding to three different forms of glycerol kinase could be observed when a PEP concentration between 1 and 8 µM was used for the phosphorylation assays (Fig. 3d, lane 6). Under these conditions, only some of the glycerol kinase molecules could be phosphorylated, and in addition to the two bands migrating to the positions of unphosphorylated and completely phosphorylated glycerol kinase, a third band migrating between these two bands could be observed. In contrast, only bands corresponding to phosphorylated and unphosphorylated glycerol kinase, but no third band, was observed when reaction mixtures containing between 1 and 8 µM PEP were separated on SDS polyacrylamide gels (data not shown). Since bacterial glycerol kinases are known...
to be composed of identical subunits (Hurley et al., 1993), we supposed that the third band observed on non-denaturing gels after separation of phosphorylation mixtures containing low concentrations of PEP corresponds to glycerol kinase molecules in which not all subunits are phosphorylated. By carrying out size-exclusion chromatography on an FPLC column (Superdex 200 pg; Pharmacia) with high resolution in the
100 kDa range, we could demonstrate that native \textit{T. flavus} glycerol kinase is composed of two identical subunits and not, as has previously been reported, four subunits (Huang \textit{et al.}, 1997). It is therefore likely that the third band observed only on non-denaturing polyacrylamide gels after separation of phosphorylation mixtures containing limiting amounts of PEP and migrating between unphosphorylated and completely phosphorylated glycerol kinase (Fig. 3d, lane 6) corresponds to glycerol kinase dimers in which only one of the two subunits is phosphorylated.

**Effect of phosphorylation of \textit{T. flavus} glycerol kinase on its enzyme activity.**

PEP-dependent, enzyme I- and HPr-catalysed phosphorylation of enterococcal glycerol kinases caused a 10-fold increase in enzyme activity (Deutscher, 1985; Charrier \textit{et al.}, 1997). We therefore wanted to test whether phosphorylation of \textit{T. flavus} glycerol kinase would lead to a similar stimulation with regard to its enzyme activity. \textit{T. flavus} glycerol kinase was phosphorylated with PEP, enzyme I and HPr as described in Methods, and glycerol kinase assays were carried out using saturating concentrations of glycerol (5 mM) and ATP (5 mM). The $K_m$ values of \textit{T. flavus} glycerol kinase for glycerol and ATP have been reported to be 38 and 162 $\mu$M, respectively (Huang \textit{et al.}, 1997). Under the above conditions, very similar activities were found for unphosphorylated (44 units) and phosphorylated glycerol kinase (5-6 units). In contrast to enterococcal glycerol kinases, phosphorylation of \textit{T. flavus} glycerol kinase does not seem to increase the $V_{\text{max}}$ of this enzyme. The observed absence of a stimulatory effect of PEP-dependent phosphorylation of glycerol kinase on its enzyme activity cannot be due to incomplete phosphorylation of \textit{T. flavus} glycerol kinase under the reaction conditions employed. When an aliquot of the phosphorylated \textit{T. flavus} glycerol kinase used for the assay was separated on SDS polyacrylamide gels, more than 90% of the glycerol kinase was found to be present in the phosphorylated form (data not shown).

**DISCUSSION**

When proteins with identical function from \textit{T. flavus} and \textit{B. subtilis} were compared, they exhibited sequence identities between 30 and 50% (data not shown). The much higher degree of sequence identity observed for the glycerol kinases (80-60%) and the N-terminal 156 amino acid fragment of the glycerol facilitators (64-0%) from these two distantly related organisms suggested that \textit{T. flavus} might have gained the \textit{glp} operon by horizontal gene transfer from a bacillus species or an organism closely related to bacilli. The \textit{glp} operon seems to be expressed in \textit{T. flavus} and both proteins encoded by the \textit{glp} operon seem to be active, as glycerol kinase activity can be detected in crude extracts of \textit{T. flavus} cells and as \textit{T. flavus} cells can transport glycerol. Glycerol transport was found to be reduced when cells were grown in the presence of glucose. Our experiments do not exclude the possibility that glucose exerts its repressive effect not on glycerol transport directly but on an early step of glycerol metabolism. Since glycerol is transported by facilitated diffusion, inhibition of its first metabolic steps will probably also reduce the uptake of glycerol.

Most glycerol kinases from Gram-positive bacteria, but not glycerol kinases from Gram-negative bacteria, seem to be regulated by a mechanism that implicates stimulation of glycerol kinase activity by PEP-dependent phosphorylation at a histidyl residue catalysed by enzyme I and HPr of the PTS (Deutscher \& Sauerwald, 1986; Charrier \textit{et al.}, 1997). As a consequence, \textit{ptsH} or \textit{ptsI} mutants ofGram-positive bacteria, in which glycerol kinase cannot be activated by PEP-dependent phosphorylation, were unable to grow on glycerol as the sole carbon source (Reizer \textit{et al.}, 1984; Romano \textit{et al.}, 1990; Gonzy-Treboul \textit{et al.}, 1991; Beijer \& Rutberg, 1992). Interestingly, the phosphorylatable histidyl residue was also found to be present in glycerol kinase from \textit{T. flavus}. The sequences flanking this histidyl residue are well-conserved when compared to the corresponding sequences of glycerol kinase from \textit{B. subtilis} (Fig. 2) or other Gram-positive bacteria. In the presence of [\textsuperscript{32}P]PEP, purified \textit{T. flavus} glycerol kinase was found to be phosphorylated by crude extracts of \textit{T. flavus} cells (Fig. 3a), suggesting that this organism contains the general PTS proteins enzyme I and HPr. This assumption was confirmed by the observation that crude extracts prepared from \textit{T. flavus} cells were capable of reconstituting the lactose-specific PTS activity in mutant complementation assays with \textit{S. aureus} \textit{ptsI} and \textit{ptsH} mutants (Hengstenberg \textit{et al.}, 1969). Deinococcus radiodurans, a close relative of \textit{T. flavus}, was found to possess a multiphosphoryl transfer protein (MTP) similar to Rhodobacter capsulatus (Wu \textit{et al.}, 1990) and Xanthomonas campesiris (de Crécy-Lagard \textit{et al.}, 1995). The MTP is part of the fructose-specific PTS and contains an enzyme IIA\textsubscript{Fru} domain followed by an HPr and an enzyme I domain. The sequence around the phosphorylatable histidyl residue in the HPr domain of \textit{D. radiodurans} was found to exhibit strong similarity to the corresponding sequence in \textit{B. subtilis} HPr (data not shown). However, the experiments presented in Fig. 3a suggest that \textit{T. flavus} does not possess an MTP, but that enzyme I and HPr of this organism are probably distinct proteins, as radioactive bands migrating to the approximate positions of enzyme I and HPr from \textit{B. subtilis} were detected when crude extracts of \textit{T. flavus} were incubated with [\textsuperscript{32}P]PEP and separated by SDS-PAGE. Even in fructose-grown cells (Fig. 3a, lanes 8 and 9), no labelled band migrating to the position corresponding to the molecular mass of the MTP (90 kDa) was observed. However, similar to the HPr domain of \textit{D. radiodurans} MTP, HPr of \textit{T. flavus} probably possesses an active centre strongly resembling the active centre of HPr in Gram-positive bacteria, which would explain why HPr present in crude extracts prepared from \textit{T. flavus} cells is functional in the \textit{S. aureus} mutant-
complementation assay with the \textit{ptsH} mutant S797A and why P-His-HPr from both \textit{B. subtilis} and \textit{T. flavus} can efficiently phosphorylate \textit{T. flavus} glycerol kinase. Although phosphorylation of glycerol kinase changes the electrophoretic mobility of \textit{T. flavus} glycerol kinase in a similar way to that which has been observed for glycerol kinase from \textit{Ent. faecalis} (Deutscher & Sauerwald, 1986; Charrier et al., 1997), only a very weak stimulation of glycerol kinase activity was found to accompany phosphorylation of \textit{T. flavus} glycerol kinase. The physiological function of the PEP-dependent PTS-catalysed phosphorylation of \textit{T. flavus} glycerol kinase therefore remains unknown. It is interesting to note that glycerol kinase from another thermophilic organism, \textit{Bacillus steatorhermobilus}, exhibited a very similar behaviour to \textit{T. flavus} glycerol kinase. It was also phosphorylated by PEP, enzyme I and HPr, and phosphorylation caused changes in electrophoretic mobility identical to those found with \textit{T. flavus} glycerol kinase (Reizer & Peterkosky, 1987). In addition, no increase in enzyme activity was observed when \textit{B. steatorhermobilus} glycerol kinase became phosphorylated. It is possible that phosphorylation of glycerol kinase in the two thermophilic organisms \textit{T. flavus} and \textit{B. steatorhermobilus} causes an increase in enzyme activity only at higher temperatures. Since no thermostable glycerol-3-phosphate dehydrogenase was available, the enzyme assays reported in this paper were carried out at 37 °C and not at the preferred temperature of \textit{T. flavus}, i.e. 60 °C. It is interesting to note that when phosphorylated glycerol kinase from \textit{T. flavus} was kept at 60 °C in Tris/HCl buffer, pH 7.4, about 70% of the protein was dephosphorylated within 10 min, as was observed with other proteins phosphorylated at the N-3 position of a histidyl residue (Waygood et al., 1986). However, the remaining 30% of the protein was found to remain phosphorylated even after 1 h incubation at 60 °C (data not shown). It is possible that under physiological conditions, most of the \textit{T. flavus} glycerol kinase is converted into this phosphorylated, heat-resistant form, which might exhibit elevated enzyme activity.

After this paper was accepted, we noticed when carrying out BLAST searches with the amino acid sequence of \textit{T. flavus} glycerol kinase in microbial databases that \textit{D. radiodurans}, a close relative of \textit{T. flavus}, contains two glycerol kinases: one without the conserved phosphorylatable histidyl residue of Gram-positive bacteria, rather resembling \textit{Es. coli} glycerol kinase (58% sequence identity), the other possessing an equivalent of His-232 and exhibiting an unexpectedly high sequence identity of 88% to glycerol kinase from \textit{Streptococcus pyogenes}. \textit{D. radiodurans} possesses an MTP, which is composed of a fructose-specific EIIA, an HPr and an enzyme I domain (Wu et al., 1990). It is therefore likely that the His-232-containing glycerol kinase of this organism is also phosphorylated \textit{in vivo} with PEP.

**ACKNOWLEDGEMENTS**

We are thankful to Dominique Le Coq for critically reading the manuscript. This research was supported by the Centre National de la Recherche Scientifique, the Institut National Agronomique, Paris-Grignon and by the Institut National de la Recherche Agronomique. Preliminary \textit{D. radiodurans} sequence data were obtained from The Institute for Genomic Research through the website at http://www.tigr.org. Sequencing of the \textit{D. radiodurans} project was accomplished with the support from the US Department of Energy.
