Interrelations Between Two Pathways of Methionine Biosynthesis in *Aerobacter aerogenes*

BY J. F. MORNINGSTAR, JUN. AND R. L. KISLIUK

Department of Pharmacology, Tufts University School of Medicine, Boston, Massachusetts, U.S.A.

*(Received 9 October 1964)*

**SUMMARY**

Two pathways for methionine methyl formation, one cobalamin-dependent and one cobalamin-independent, corresponding to those observed in *Escherichia coli* PA 15 have been found in *Aerobacter aerogenes*. An initial difficulty in showing the cobalamin-dependent pathway in cell-free extracts proved to be due to the presence of enzymes which caused the removal of adenosylmethionine, a cofactor required for this system. In contrast to *E. coli* PA 15, *A. aerogenes* contains holocobalaminmethyltransferase even when grown in the absence of cobalamin. When cobalamin is added to the growth medium, the cobalamin-independent pathway is repressed.

**INTRODUCTION**

*Escherichia coli* has two enzymic mechanisms of methyl group transfer from 5-methyltetrahydropteroylglutamate derivatives to homocysteine to form methionine (Woods, Foster & Guest, 1964). A major difference in these two pathways is that one shows a requirement for a cobalamin derivative and the other does not (Kisliuk & Woods, 1960; Kisliuk, 1961). The cobalamin-requiring system also requires reduced flavin adenine dinucleotide and adenosylmethionine as cofactors (Rosenthal & Buchanan, 1963; Buchanan et al. 1964). Either 5-methyltetrahydropteroylglutamate or 5 methyltetrahydropteroylglutamate can serve as methyl donor. The cobalamin-independent pathway does not require adenosylmethionine or reduced flavin adenine dinucleotide and will utilize only 5-methyltetrahydropteroylglutamate as methyl donor (Guest, Friedman & Foster, 1962).

To demonstrate the cobalamin-dependent system the vitamin must be added to the growth medium or to enzymic extracts. Lacking a cobalamin supplement, *Escherichia coli* PA 15 does not synthesize detectable holocobalaminmethyltransferase (Kisliuk, 1961) although apoenzyme is readily demonstrable (Guest, Friedman, Dilworth & Woods, 1964). A role for cobalamin has not as yet been established for any reaction in *E. coli* other than methionine biosynthesis. *Aerobacter aerogenes* was selected for further study because this organism has been shown to require a cobalamin derivative for the dioldehydrase reaction (Lee & Abeles, 1968). The relative amounts of methionine synthesis were determined under various conditions of growth.
METHODS

Organisms. The strain of Aerobacter aerogenes (ATCC 8724) used in these studies was the same organism as used to study the cobamide coenzyme requiring dioldehydrase reaction (Lee & Abeles, 1963). Escherichia coli PA 15 is an auxotroph which requires serine or glycine for growth.

Growth conditions. The glucose inorganic salts medium of Davis & Mingioli (1950) was used for the growth of Aerobacter aerogenes. This medium was supplemented with 4 μg. cobalamin/l. when cobalamin-grown organisms were required. Growth was aerobic for 17 hr at 37°. The inoculum was 10 ml. of a 24 hr culture per 15 l. medium. The organisms were harvested in a refrigerated Sharples centrifuge.

Escherichia coli was grown in the same way except that the medium was supplemented with glycine (0.8 g./l.).

The organisms were maintained on agar slopes prepared from the media indicated.

Preparation of extracts. Acetone-dried organisms were prepared and extracted as described by Kisliuk & Woods (1960) except that 1 g. dried organisms were extracted with 20 ml. water and the extracts were not dialysed. Sonic extracts were prepared and fractionated as described by Kisliuk (1961).

The Escherichia coli holocobalaminmethyltransferase used in the present work was an ammonium sulphate fraction (0-85 % saturation) of a sonic extract of cobalamin-grown organisms (Kisliuk, 1961) containing 16 mμg. cobalamin/mg. protein. An amount of material containing 22 mμg. cobalamin was added to each incubation mixture where indicated.

Conditions for methionine synthesis in enzyme extracts. The standard reaction mixture used to study the overall formation of methionine from serine and homocysteine via 5-methyltetrahydrofolate consists of diphosphopyridine nucleotide 5 × 10⁻⁴ M, adenosine triphosphate 5 × 10⁻³ M, pyridoxal phosphate 5 × 10⁻⁴ M, fructose-1,6-diphosphate 5 × 10⁻³ M, MgSO₄ 5 × 10⁻³ M, L-serine 5 × 10⁻³ M, DL-homocysteine 10⁻⁸ M, potassium phosphate (pH 7.8) 7.5 × 10⁻⁸ M.

The reaction mixtures (2 ml. final volume) were incubated for 4 hr at 37° in Thunberg tubes filled with hydrogen. The reaction was stopped by placing the tubes in a boiling water bath for 3 min. After centrifuging down the precipitate, the supernatant fluid was assayed for methionine.

Assays. L-Methionine was determined microbiologically with Leucomostoc mesenteroides (ATCC 8042) by using Difco methionine assay medium. Cobalamin was determined with Lactobacillus leichmannii (ATCC 7880) by using Difco B₁₂ assay medium. The thymidine content of all samples was negligible as determined after destroying cobalamin by autoclaving samples in 0.2 N-NaOH for 30 min.

Protein was determined spectrophotometrically (Layne, 1957).

Materials. Adenosine triphosphate, diphosphopyridine nucleotide, flavin adenine dinucleotide and fructose-1,6-diphosphate were products of the Sigma Chemical Company. S-Adenosyl-L-methionine iodide was obtained from the California Corporation for Biochemical Research. Pteroylglutamic acid was supplied by Lederle Laboratories through the courtesy of Dr T. H. Jukes. Tetrahydropteroylglutamic acid was prepared by catalytic reduction (Kisliuk, 1957). Tetrahydropteroylglutamate was prepared similarly except that 10 mg. were reduced with
Methionine synthesis in A. aerogenes

10 mg. catalyst in 10 ml. glacial acetic acid. After removal of the catalyst by filtration under hydrogen the acetic acid was removed by lyophilization.

RESULTS

Methionine synthesis by bacterial suspensions

Suspensions of Aerobacter aerogenes and Escherichia coli PA 15 were tested for their ability to synthesize methionine from homocysteine, with serine as the precursor of the methyl group under conditions similar to those described by Gibson & Woods (1960). These workers observed that cobalamin added to suspensions of organisms grown in the absence of cobalamin stimulated methionine synthesis. When cobalamin was included in the growth medium, the harvested organisms no longer were stimulated by its addition (Table 1). Suspensions of organisms grown in the absence of cobalamin synthesized considerably more methionine when cobalamin was added to the suspending medium than did the corresponding cobalamin-grown organisms. This suggests that when the cobalamin-dependent pathway operates maximally during growth the cobalamin-independent pathway is repressed. When cobalamin was added to suspensions of organisms grown in its absence, it probably combined with apocobalaminmethyltransferase present in the organisms, thus enabling them to synthesize methionine by both pathways simultaneously. The results given in Table 1 are in agreement with the conclusion of Rowbury & Woods (1961) that substances which enhance methionine synthesis during growth decrease the ability of suspended organisms to synthesize this amino acid.

Table 1. Methionine synthesis by suspensions of Aerobacter aerogenes and Escherichia coli

The suspending medium consisted of potassium phosphate, (pH 7.4), 0.1 M; DL-homocysteine, 0.01 M; d-glucose, 0.02 M; and where indicated L-serine, 0.005 M; cobalamin 7 x 10^{-4} M. The organisms added were equivalent to 7 mg. dry weight/ml. Incubated at 37° for 3 hr.

Methionine synthesis by extracts of Aerobacter aerogenes

With extracts of acetone-dried Aerobacter aerogenes grown in the absence of cobalamin, substantial synthesis of methionine occurred, this synthesis being inhibited by the addition of tetrahydropteroylglutamate (Table 2). However, this
inhibition was not annulled by the addition of cobalaminmethyltransferase as it is in the corresponding *Escherichia coli* PA 15 system (Kisliuk, 1961). With extracts of cobalamin-grown *Aerobacter aerogenes*, methionine synthesis was very small and was further suppressed by tetrahydropteroylglutamate. This again contrasts with the situation in *Escherichia coli* PA 15 where methionine synthesis in extracts of cobalamin-grown organisms was not inhibited by tetrahydropteroylglutamate (Kisliuk & Woods, 1960). These results are consistent with the suggestion above that the presence of cobalamin in the growth medium repressed the cobalamin-independent pathway. Earlier evidence obtained with *E. coli* PA 15 (Kisliuk & Woods, 1960) on the effect of cobalamin in the growth medium in depressing methionine synthesis in extracts may be interpreted in the same manner. Cobalamin-methyltransferase, although present, was not active in extracts of *Aerobacter aerogenes* under the conditions used for Table 2 (see below).

Table 2. *Inhibition of methionine synthesis by tetrahydropteroylglutamate*

The standard reaction mixture was incubated with extracts of *Aerobacter aerogenes* prepared from acetone-dried organisms grown without or with added cobalamin (3-5 mg. protein/incubation in each case). Tetrahydropteroylglutamate 1.8 x 10^-4 M.

The complete system consisted of the standard reaction mixture supplemented with flavin adenine dinucleotide and tetrahydropteroyltriglutamate (both 1 x 10^-4 M). An extract of acetone-dried *A. aerogenes* (grown in the absence of cobalamin) treated with Sephadex G-90 was used as a source of enzyme (3-8 mg. protein added).

Requirements for methionine synthesis in *Aerobacter aerogenes*

Extracts of acetone-dried *Aerobacter aerogenes* (grown in the absence of cobalamin) when treated with Sephadex G-50 (Kisliuk, 1960) and supplemented with all the required cofactors except a folate derivative, showed a negligible methionine
Methionine synthesis in *A. aerogenes*

As observed with *Escherichia coli* PA 15 (Kisliuk & Woods, 1960) tetrahydropteroylglutamate did not promote methionine synthesis but tetrahydropteroyltriglutamate did reactivate the system (Jones, Guest & Woods, 1961). The additional requirements for the *A. aerogenes* system are shown in Table 3.

In this experiment an absolute requirement was observed only for the substrates serine and homocysteine. The extract was only partially depleted of tetrahydropteroyltriglutamate, diphosphopyridine nucleotide, fructose-1,6-diphosphate, pyri-

doxal phosphate, Mg$^{2+}$ and flavin adenine dinucleotide. A requirement for adenosine triphosphate would not be expected since the cobalamin-independent pathway proceeds without this cofactor (Guest *et al.* 1962).

Inhibition of the cobalaminmethyltransferase reaction by extracts of *Aerobacter aerogenes*

When extracts of *Aerobacter aerogenes* and *Escherichia coli* PA 15 were mixed under conditions appropriate for the expression of the cobalamin-independent pathway (Table 4, part (a)) methionine synthesis occurred. When cobalaminmethyltransferase was added (Table 4, part (b)) to *E. coli* extracts, methionine synthesis was greatly stimulated, probably because both pathways were operating simultaneously. There was no corresponding stimulation in *A. aerogenes* extracts nor in a
mixture of *A. aerogenes* and *E. coli* PA 15 extracts. The cobalaminmethyltransferase was apparently inactive in the presence of *A. aerogenes* extracts. This suggestion is substantiated by the results obtained under conditions where the cobalamin-independent pathway was inhibited and only the cobalamin dependent pathway operates, i.e. in the presence of tetrahydropteroylglutamate (Table 4, part (c)). The addition of *A. aerogenes* extract under these conditions greatly decreased methionine synthesis.

**Table 4. The effects of extracts of Aerobacter aerogenes on methionine synthesis by Escherichia coli extracts**

The standard reaction mixture was incubated with extracts of acetone-dried *A. aerogenes* on *E. coli* (grown in the absence of cobalamin) 5.3 and 4.2 mg. protein per incubation, respectively. When the extracts were combined half of each amount was added. Tetrahydropteroylglutamate $1.8 \times 10^{-4} \text{ M}$ where indicated.

**The nature of the inhibitor in Aerobacter aerogenes extracts**

When extracts of *Aerobacter aerogenes* were heated for 5 min. at 100° they were no longer inhibitory, suggesting that the inhibitor is an enzyme. It was considered that the inhibition might be due to enzymic removal of methionine; however, this appeared not to be the case since added methionine was recovered at the end of the incubation (Table 5). It was then observed that the inhibition was annulled by the addition of adenosylmethionine (Table 5). It seems likely therefore that the inhibition of cobalaminmethyltransferase by *A. aerogenes* extracts was due to the ability of these extracts to metabolize adenosylmethionine which is required for this
Methionine synthesis in *A. aerogenes*

System in catalytic amounts. Shapiro (1962) observed that extracts of this organism metabolized adenosylmethionine by (1) methylating homocysteine to methionine and adenosylhomocysteine, and (2) decomposition to adenine, methylthioribose and homoserine. The results of Table 5 indicate that the former reaction might account for 20% of the breakdown of adenosylmethionine (30 of 150 μmole). The remainder was presumably destroyed by the latter reaction.

**Isolation of cobalaminmethyltransferase from Aerobacter aerogenes** grown in the absence and presence of cobalamin

To show conclusively the presence of cobalaminmethyltransferase in extracts of *Aerobacter aerogenes*, sonic extracts were fractionated with ammonium sulphate and calcium phosphate gel by the method of Kisliuk (1961). The distribution of

* To determine this value, the fraction was added at various concentrations to an assay system containing the standard reaction mixture + tetrahydropteroylglutamate (1.8 x 10⁻⁴ M), an extract of acetone-dried *E. coli PA* 15 (7 mg. protein) and *E. coli PA* 15 cobalaminmethyltransferase. In each case the inhibition could be annulled with adenosylmethionine.

† Results with these fractions are shown in Table 7.
‡ Results with these fractions are shown in Fig. 2.

cobalamin in these fractions (Table 6) was similar to that obtained with cobalamin-grown *Escherichia coli* (Kisliuk, 1961). Only fraction 6 (Table 6) appeared to be entirely free from inhibitor (Table 7). Fractions 7, 14, 15 showed inhibition which
was annulled with adenosylmethionine (Table 7, Fig. 2). In subsequent trials fractions equivalent to fraction 14 were also obtained free from inhibitor.

Two fractions (Table 7) obtained from organisms grown in the absence of cobalamin were tested for cobalaminmethyltransferase activity (adenosylmethionine added) separately. Activity was demonstrable in both fractions, showing that holocobalaminmethyltransferase was endogenously synthesized. In other organisms so far studied, *Escherichia coli* (Kisliuk, 1961), pigs (Loughlin, Elford & Buchanan, 1964) and chickens (Dickerman, Redfield, Bieri, & Weissbach, 1964), it is formed from exogenous cobalamin.

**Table 7. Assay of fractions of Aerobacter aerogenes grown in the absence of cobalamin for cobalaminmethyltransferase activity**

Assay conditions are the same as described in Table 5. Incubations 1 to 5 contain adenosylmethionine at 7.5 x 10^{-4} M.

The cobalamin content of the various fractions was considerably enhanced by growth on cobalamin. However, the specific activity did not change. The µmoles methionine formed per µg cobalamin when 5 µg cobalamin was added to the assay system was 61 for the material prepared from cobalamin grown organisms (Fig. 2) and 57 for the corresponding preparations from organisms grown in the absence of cobalamin (Table 7). The activity of the *Escherichia coli* preparation used in the present work (12 µmoles/µg.) was somewhat lower because of deterioration in storage.

**DISCUSSION**

During this work, the late Professor D. D. Woods kindly informed us of experiments made in his laboratory in which methylcobalamin served as a methyl donor to homocysteine when incubated with extracts of *Aerobacter aerogenes*. This provides further evidence that cobalaminmethyltransferase is present in this organism. Although the cobalamin-dependent pathway was inactive in extracts because of removal of adenosylmethionine it apparently does function in vivo, otherwise one would not expect the observed repression of the cobalamin-independent pathway due to increased synthesis of methionine in cobalamin-grown organisms.

One of us (R.L.K.) is indebted to the Leukemia Society for a scholarship. The work was supported by a grant from the National Science Foundation (U.S.A.). We thank Mr Kenneth Skala for help with some of the experiments.
Methionine synthesis in A. aerogenes
